TABLE 15.5: Comparison of conditions involving bone metabolism.

Condition	*Calcium*	*Phosphorus*	*Vitamin D*	*Alkaline phosphatase (ALP)*	*Parathormone*	*Bone*
Rickets/Osteomalacia	Decreased	Decreased	Low	Elevated	Elevated	Softening, Looser's zones
Osteopenia	Normal	Normal	Normal	Normal/decreased	Normal	Decrease bone mass
Osteoporosis	Normal	Normal	Normal/ decreased	Normal/mild elevation	Normal	Degeneration of bone matrix
Hyperparathyroidism	Increased	Decreased	Normal	Elevated	Elevated	Brown tumor, lytic lesions
Paget's disease	Normal	Normal	Normal	Variable	Variable	Osteolytic/sclerotic lesion

- **Prevention:**
  - ▪ Adequate consumption of vitamin D (1,000–5,000 IU/day)
  - ▪ Adequate exposure to sunlight (from 30 minutes to 2 hours/week for infants).

Treatment of rickets

- Treat the underlying cause.
- Supplementation diet with calcium and vitamin D.
- **For nutritional deficiency** of vitamin D: Ergocalciferol, 1,50,000–6,00,000 IU orally or intramuscularly as a single dose. Or give Ergocalciferol in a dose of 2,000 IU every day.

Osteomalacia

Q. Discuss the causes, clinical features, investigations, and treatment in case of osteomalacia.

- Vitamin D deficiency in **adults** is accompanied by hypocalcemia and hypophosphatemia which result in **impaired mineralization of bone matrix** proteins, a condition known as osteomalacia.

- Thus, it is a disorder of mineralization of the organic matrix of the skeleton in adults when the **epiphyseal growth plates have closed**. In contrast, in rickets, the growing skeleton is involved.

Causes of osteomalacia are listed in **Box 15.5.**

Box 15.5: Causes of osteomalacia.

- **Nutritional abnormalities:** Dietary deficiency of vitamin D, parenteral nutrition
- **Malabsorption:** Tropical sprue, celiac disease, hepatobiliary diseases, pancreatic insufficiency
- **Disorders of vitamin D metabolism:** Vitamin D dependency type I and type II, anticonvulsants, chronic renal failure
- **Acidosis:** Distal renal tubular acidosis (type I)
- **Phosphate depletion:** Use of nonabsorbable antacids, tumor associated osteomalacia
- **Others:** Multiple myeloma, nephrotic syndrome, lead poisoning, inadequate sun exposure

Clinical Features

- **Bone pains, muscle weakness, fractures** of bones with minor trauma.
- Pain in the hip may cause **antalgic gait**.
- **Weakness of proximal muscle** results in waddling gait and may resemble primary muscle disease.
- **Collapse of vertebrae** causes local pain and deformity.
- Softening of skeleton may produce deformities such as **kyphosis, coxa vara, pigeon chest** and **triradiate pelvis** with a narrow pubic arch.

Laboratory Investigations

Blood (same as for rickets).

Urinary excretion of calcium: Reduced.

Radiological findings

- **Bone density:** Reduced (osteopenia), diffuse demineralization.
- **Epiphyseal growth plate:** Increased in thickness, cupped and hazy at the metaphyseal border.
- **Cortical thinning:** Due to secondary hyperparathyroidism.
- **Other features:** Presence of nontraumatic fractures, radiolucent bands called pseudofractures **(Looser's zones) (Fig. 15.8).**
- **Bone scan** may be normal or show discrete foci of increased radionuclide uptake.
- **Bone mineral density** as assessed by dual-energy X-ray absorptiometry (DEXA) is reduced at spine, hip and forearm, with the maximum deficits at the cortical-rich bone in the forearms.

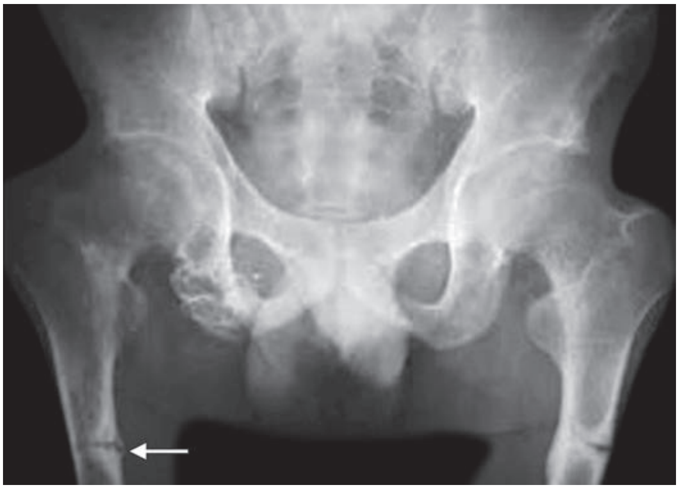

FIG. 15.8: X-ray shows Looser's zones (arrow) and osteopenia.

Treatment of osteomalacia

- **Treat the underlying cause** wherever possible.
- **Dietary deficiency:** It is corrected by 1,000–4,000 IU of vitamin D_2 (ergocalciferol) or vitamin D_3 (cholecalciferol) for 3 months. This is followed by lower doses as maintenance. Vitamin D should be taken with fatty diet for maximum absorption.
- **Osteomalacia due to malabsorption:** Give 50,000–1,00,000 IU of vitamin D + calcium supplementation. Small doses of calcitriol (0.5–1.0 µg daily) also effective.

Role of Vitamin D in Health and Disease

It has been shown in **Table 15.6.**

Hypervitaminosis D

Q. PE12.7 Describe the causes, clinical features, diagnosis and management of excess of vitamin D (hypervitaminosis D).

Hypervitaminosis D causes hypercalcemia, which manifests as:

- Nausea and vomiting
- Excessive thirst and polyuria
- Severe itching
- Joint and muscle pains
- Disorientation and coma
- Metastatic calcifications

Treatment of hypervitaminosis: Hydration and treatment of hypercalcemia.

TABLE 15.6: Role of vitamin D in health and disease.

Parathyroid hormone	Hypovitaminosis D causes secondary hyperparathyroidism which increases the risk of MI, HTN, and stroke
Malignancy	➢ Transcription of oncogenes involved in cell differentiation and proliferation is controlled: (c-myc, c-fos, c-sis) ➢ There is an inverse relationship between sun exposure and cancer mortality ➢ 10 ng/mL rise in vitamin D level of associated with—17% reduction in cancer incidence, 29% reduction in all cancer mortality, and 45% reduction in GI cancer mortality
Nervous system function	➢ Vitamin D modulates neurotransmitter and neurological function ➢ Has anticonvulsant and antidepressant effect ➢ 50% of multiple sclerosis patients are vitamin D deficient ➢ Seizures are common with vitamin D deficiency
Anti-inflammatory function	➢ Suppresses and may prevent autoimmune diseases ➢ Seems to reduce severity and frequency of childhood pneumonias
Calcium homeostasis	➢ Calcium absorption increases as 25(OH) vitamin D blood levels increase
Cardiovascular function	➢ Risk of myocardial infarction doubles in patients with vitamin D deficiency ➢ Heart failure patients have much lower vitamin D levels ➢ HTN patients given UV light treatments 3 times/week for 6 weeks have shown mild decrease in BP
Diabetes type 1	➢ Infants and children who were supplemented with had decreased incidence of DM type 1 by 80%
Diabetes type 2	➢ Low vitamin D levels associated with insulin resistance and β-cell dysfunction ➢ Postprandial glucose and insulin sensitivity are better in healthy adults with highest vitamin D levels ➢ Highest vitamin D levels associated with 60% improvement in insulin sensitivity
Respiratory system	➢ Vitamin D supplementation provides significant protective effect against influenza ➢ It is also associated with decrease in FEV1 ➢ Increased incidence of rhino-bronchial atopy
Osteoarthritis (OA)	Vitamin D deficiency hastens the progression of OA hip and knee
Mood disorders	Vitamin D supplementations improves general mood and hastens recovery in seasonal affective mood disorders
Polycystic ovary syndrome	Deficiency exists in 60% of cases with normalization of menses and/or fertility within 3 months of supplementation
Pain	➢ Persistent, nonspecific musculoskeletal pain in 93% of patients had vitamin D deficiency ➢ Low back pain patients (53%) have vitamin D deficiency
Autoimmune disease	Vitamin D insufficiency in half of the patients with fibromyalgia + systemic lupus erythematosus (SLE), Graves' disease, ankylosing spondylitis and rheumatoid arthritis
Falls in the elderly	➢ Vitamin D deficiency reported to affect predominantly the weight-bearing antigravity muscles of the lower limb, which are necessary for postural balance and walking ➢ Improvement in lower extremity muscle strength and balance with vitamin D supplementation thought to explain the reduced number of fall-related fractures

VITAMIN E (ALPHA TOCOPHEROL)

Q. PE12.12 Describe the causes, clinical features, diagnosis and management of deficiency of vitamin E.

- **Sources:** Almonds, vegetable oils, and cereals
- **Actions:**
  - Acts as free radical scavenger and **antioxidant**
  - **Protects** LDL and PUFA in **membranes from oxidation**
  - **Inhibits prostaglandin synthesis**, activities of phospholipase A2, and protein kinase C.

Deficiency

- **Causes:**
  - Pancreatic exocrine insufficiency
  - Cholestatic liver disease
  - Extensive resection or disease affecting small intestine
  - Ataxia with vitamin E deficiency, due to a mutation in the gene encoding hepatic alpha-tocopherol transfer protein (*TTPA*)
  - Abetalipoproteinemia, due to mutations in the microsomal triglyceride transfer protein.
- **Diagnosis:**
  - **Alpha-tocopherol levels** of <0.5 mg/dL (5 mg/mL or 11.5 mmol/L)—deficiency.
  - For patients with marked hyperlipidemia, effective serum vitamin E level = alpha-tocopherol (mg)/total lipids (g); where total lipids = cholesterol + triglycerides.
  - A normal result is >0.8 mg.

- **Clinical manifestations:**
  - **Spinocerebellar syndrome**—ataxia, hyporeflexia, and loss of proprioceptive and vibratory sensation.
  - Ophthalmoplegia, skeletal myopathy, pigmented retinopathy.
  - Brown bowel syndrome (**intestinal lipofuscinosis**) is a brown pigmentation of the bowel that occasionally presents with bowel dilatation and pseudo-obstruction (due to lipofuscin accumulation within the smooth muscle mitochondria).
  - Lifespan of red blood cells is shortened.
  - In premature infants, vitamin E deficiency may cause a **hemolytic anemia**.

Treatment

- For infants and children: 17–35 mg/kg/day of RRR-alpha-tocopherol.
- For adults: 800–1200 mg/day.

VITAMIN K

Q. PE12.13 Discuss the RDA, dietary sources of vitamin K and their role in health and disease.

Q. PE12.14 Describe the causes, clinical features, diagnosis, management and prevention of deficiency of vitamin K.

- **Sources:**
  - Dietary vitamin K_1 (**phylloquinone**) is found in green vegetables like spinach and broccoli, and in some oils.
  - Vitamin K_2 (**menaquinone**) is found in bacterial flora, meat (especially liver), cheeses, fermented soybeans, and eggs.
- **Actions:**
  - **Coagulation**: Vitamin K is essential for activity of several carboxylase enzymes within hepatic cells, and therefore is necessary for the activation of coagulation factors **VII, IX, X, and prothrombin.**
  - Activation of proteins C and S
  - Reversal of coumarin-like anticoagulants
  - Bone formation
  - Coronary vascular calcification
  - COVID-19: Vitamin K preferentially actives hepatic procoagulant pathways over extrahepatic anticoagulant protein S. Vitamin K also activates matrix Gla protein (MGP), which protects vascular and pulmonary endothelium.

Deficiency

- **Causes:**
  - Cystic fibrosis
  - Primary biliary cholangitis
  - Primary sclerosing cholangitis
  - Biliary atresia
  - Familial intrahepatic cholestasis and other inherited disorders associated with cholestasis
  - Malabsorption syndromes
  - Liver failure
  - Medications: 2nd, 3rd generation cephalosporins, orlistat
  - Very high doses of vitamin E can cause vitamin K deficiency
- **Clinical manifestations:**
  - Easy bruising
  - Mucosal bleeding
  - Splinter hemorrhages
  - Melena
  - Hematuria
  - Other manifestations of impaired coagulation.
- **Diagnosis:**
  - Symptomatic patients with mild deficiency—only PT is elevated; in severe deficiency—both PT and aPTT are elevated.
  - Levels of PIVKA-II (**protein induced in vitamin K absence or antagonist-II**, also known as des-gamma-carboxy prothrombin) are **more sensitive** than PT in detecting vitamin K deficiency. PIVKA-II is also elevated in the presence of vitamin K antagonist (VKA) drugs or certain tumors such as hepatocellular carcinoma.
  - Measuring **vitamin K-dependent factors** (i.e., prothrombin, factors VII, IX, X, or protein C). In patients who are vitamin K deficient, levels of these factors often are **<50%** of normal.
  - Phylloquinone levels can also be measured directly but are impractical for clinical use.

Treatment:

- Vitamin K can be administered in doses of **1–25 mg** (usually 10 mg) via oral, intramuscular, subcutaneous, or intravenous routes.
- When vitamin K deficiency occurs in patients who are also receiving coumarin-like anticoagulants, doses of vitamin K should be minimized in order to prevent refractoriness to further anticoagulation.

TRACE ELEMENTS

- The term 'trace' is used for concentrations of elements **not exceeding 250 µg/g of extracellular matrix.**
- Trace elements are **naturally occurring, homogeneous, inorganic substances** required in humans in amounts <100 mg/day.
- Classification of trace elements is presented in **Table 15.7**.
- There are about 15 trace elements of which only **10 are essential** nutrients in humans.
- These include: Iron, zinc, copper, chromium, selenium, iodine, fluorine, manganese, molybdenum, and cobalt.

TABLE 15.7: Classification of trace elements.

Essential trace elements	*Trace elements that are probably essential*	*Potentially toxic elements with possible essential functions in low doses*
➢ Iodine	➢ Manganese	➢ Fluoride
➢ Zinc	➢ Nickel	➢ Lead
➢ Selenium	➢ Silicon	➢ Cadmium
➢ Copper	➢ Boron	➢ Mercury
➢ Molybdenum	➢ Vanadium	➢ Arsenic
➢ Chromium		➢ Lithium
➢ Cobalt		➢ Tin
➢ Iron		➢ Aluminum

Iron

Q. PE13.1 Write a short note on daily requirement of iron and important dietary sources of iron.

- **Most essential** trace element.
- **Deficiency state:**
  - **Asymptomatic**
  - **Anemia** (*refer* Chapter 9), weakness, headache, irritability, and varying degrees of fatigue and exercise intolerance.

The causes of iron overload have been shown in **Box 15.6.**

Box 15.6: Causes of iron overload.

Cause

Increased intake

- Transfusional overload (e.g., in inherited bone marrow failure syndromes, hemolytic anemias, myelodysplastic syndrome, aplastic anemia)
- Iron-loaded diet (e.g., "African iron overload")
- Repeated heroin infusions (e.g., to treat acute intermittent porphyria)

Increased absorption (with normal intake)

- Hereditary hemochromatosis due to HFE mutation (e.g., C282Y/C282Y; C282Y/H63D)
- Hereditary hemochromatosis due to rare mutations (e.g., ferroportin, hemojuvelin, hepcidin, ceruloplasmin)
- Thalassemia major or intermedia
- Sideroblastic anemia (inherited or acquired)
- Inherited anemias (e.g., CDA, DBA)
- Gestational alloimmune liver disease (GALD)
- Chronic liver disease, especially alcoholic liver disease, chronic hepatitis, and nonalcoholic fatty liver disease (NAFLD)

(HFE: hereditary hemochromatosis gene; CDA: congenital dyserythropoietic anemia; DBA: Diamond-Blackfan anemia)

Acute Iron Poisoning

- Develops when iron level **exceeds 60 mg/kg elemental iron**.
- **Clinical features:**
  - Vomiting, abdominal pain, bloody diarrhea, shock, dehydration, cyanosis, acidosis, and coma
  - Can cause **hepatotoxicity** and bowel obstruction
  - **Cardiomyopathy**, heart failure, and/or arrhythmias
  - **Diabetes mellitus**
  - Hypogonadism, decreased libido, and impotence
  - Skin involvement with hyperpigmentation (the bronze color in "**bronze diabetes**")
  - **Arthropathy,** especially involving the second and third metacarpophalangeal joints, and often with chondrocalcinosis.

Treatment

- **Gastric lavage** with sodium bicarbonate solution.
- **Desferrioxamine** 15 mg/kg/h IV, increased to maximum dose of 35 mg/kg/h.
- Correction of acidosis and shock.
- Extracorporeal removal with **exchange transfusion or continuous venovenous hemofiltration**.
- **Phlebotomy** can be done if no significant anemia present.

FLUOROSIS

Q. Write short note on fluorosis and its radiological signs.

- Fluorine's **ionic form** is known as fluoride.
- It is a component of **bone mineral** and alters its physical characteristics.

- Fluoride helps to **prevent dental caries**, because it increases the resistance of the enamel to acid attack.
- Requirement in adults is between 1.5 and 4 mg/day and 96% of fluorides in the body found in **bone and teeth.**
- **Deficiency:** Intake of <0.1 mg/day in infants and <0.5 mg/day in children predisposes to an increased incidence of dental caries.
- **Toxicity:** Results in **fluorosis.** This develops when fluoride content in the water is high (>3–5 ppm).
  - **Acute** ingestion of >30 mg/kg body weight usually manifests with GI symptoms such as diarrhea, vomiting leading to renal failure and may cause death.
  - **Dental fluorosis:** It is characterized by mottling of teeth where the enamel loses its luster, teeth appear chalky white with transverse yellow bands. It becomes rough, pigmented, pitted and brittle (fluoride teeth).
  - **Skeletal fluorosis:** Its features are:
    - **Sclerosis of bones** (especially of spine, pelvis, and limbs).
    - **Calcification** of ligaments, interosseous membrane **(Fig. 15.9)**, and tendinous insertions.
    - **Osteoporosis with** brittle bones.
    - **Severe pain and stiffness** in joints, stiffness in neck and backbone, bow legs. Other features are weakness, anemia, and weight loss.

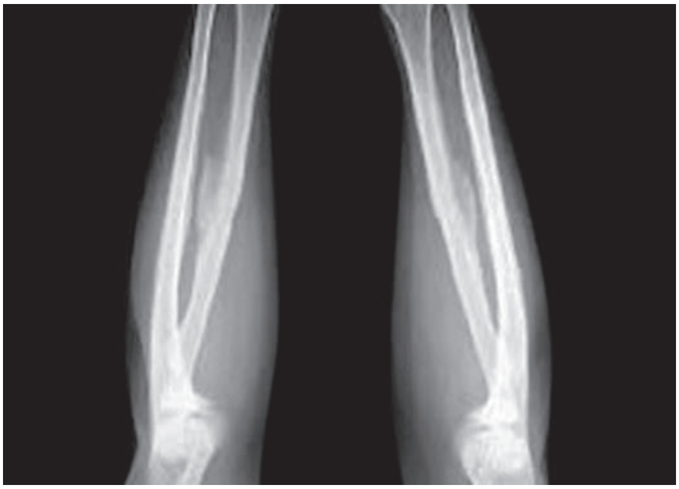

FIG. 15.9: X-ray of fluorosis showing calcification of interosseous membrane.

Angular Stomatitis

Q. Write a short note on angular stomatitis.

- **Angular stomatitis** refers to **cracking of the epithelium at the edge of the lips**.
- It presents with **erythema, maceration, scaling, and fissuring** at the corners of the mouth.
- Most commonly **bilateral** and **very painful**.
- **Causes of angular stomatitis** have been shown in **Box 15.7.**

Box 15.7: Causes of angular stomatitis.

- Iron deficiency anemia
- Secondary infection of *Candida albicans*, *Staphylococcus*
- **Vitamin deficiency:**
  - Riboflavin (B_2) deficiency
  - Pyridoxine (B_6) deficiency
  - Niacin deficiency (pellagra)
- Herpes labialis at the angle of mouth
- Angular stomatitis is associated with cheilosis in niacin deficiency and pellagra

ENTERAL AND PARENTERAL NUTRITION SUPPORT

Some form of **nutritional support** is needed for **patients who cannot eat, should not eat, will not eat or cannot eat enough.**

Q. IM23.4 Enumerate the indications for enteral and parenteral nutrition in critically ill-patients.

Indications for Nutritional Support

- **Severely malnourished patients** on admission to hospital.
- **Moderately malnourished** patients who are **not expected to eat for >3–5 days** (because of their physical illness).
- **Normally nourished** patients **not expected to eat for >5 days** or to eat less than half their intake for >8–10 days.

Types of Nutritional Support

- **Enteral nutrition** should be used, if the GI tract is functioning normally.
- **Parenteral nutrition**.

Q. Discuss the advantages and problems associated with enteral nutrition.

Enteral Nutrition

- **Prerequisite:** Must have **functioning GI tract**. Patients who are not able to swallow may need artificial nutritional support (e.g., after acute stroke or throat surgery, or long-term neurological disorders such as motor neuron disease and multiple sclerosis).
- Whenever possible, the enteral route is **preferred** and to be used.

TABLE 15.8: Advantages and disadvantages of enteral nutrition (EN).

Advantages	***Disadvantages***
➢ Intake easily/accurately monitored ➢ Provides nutrition when oral intake is not possible or adequate ➢ Less cost than parenteral nutrition ➢ Readily available ➢ Reduces risks associated with disease state ➢ Preserves gut integrity and immunologic function ➢ Decreases likelihood of bacterial translocation ➢ Increased compliance with intake ➢ Decreases the risk of multiorgan failure in ICU patients	➢ *Mechanical complications:* – Tube migration – Increased risk of bacterial contamination – Tube obstruction – Pneumothorax ➢ Costs more than oral diets ➢ Less palatable ➢ *Labor:* (1) Intensive assessment; (2) administration; (3) tube patency; and (4) site care; monitoring

TABLE 15.9: Methods of enteral nutrition.

Tube feeding <4 weeks	***Tube feeding >4 weeks***
➢ Nasogastric ➢ Nasoduodenal ➢ Nasojejunal ➢ Orogastric	➢ Enterostomy ➢ Gastrostomy ➢ Jejunostomy

- *Advantages and disadvantages of enteral nutrition have been shown in **Table 15.8.***
- *Methods of enteral nutrition have been shown in **Table 15.9**.*
- **Complications of enteral feeding:**
  - **Access problems** (e.g., tube obstruction)
  - **Administration problems** (e.g., aspiration pneumonia)
  - **Gastrointestinal complications** (e.g., diarrhea)
  - **Metabolic complications** (e.g., overhydration).
- **Rate and method of delivery***
  - **Bolus:** 300–400 mL rapid delivery via syringe several times daily
  - **Intermittent:** 300–400 mL, over 20–30 minutes, several times/day via gravity drip or syringe
  - **Cyclic:** Via pump usually at night
  - **Continuous:** Via gravity drip or infusion pump
- **Types of enteral formulations:**
  - **Standard polymeric formulas:**
    - ♦ Isotonic to serum
    - ♦ Caloric density of approximately 1 kcal/mL
    - ♦ Lactose-free
    - ♦ Protein content of about 40 g/1,000 mL (40 g/1,000 kcal)
    - ♦ Nonprotein calorie to nitrogen ratio of approximately 130
    - ♦ Mixture of simple and complex carbohydrates
    - ♦ Long-chain fatty acids (although some are now including medium-chain and omega-3 fatty acids)
    - ♦ Essential vitamins, minerals, and micronutrients
  - **Concentrated formulas:** Useful for patients requiring volume restriction. Caloric density—2.0 kcal/mL
  - **Predigested** (elemental and semielemental—previously called): Useful in thoracic duct leak, chylothorax, chylous ascites, malabsorption syndromes, nontolerance to standard enteral feeds (e.g., persistent diarrhea)
  - **Critical illness:** Special formulations for certain critical illnesses, have not proved beneficial over the others.
- **Contraindications to enteral feeding:** The intestinal tract cannot be used effectively in some patients because of the following:
  - Persistent nausea or vomiting
  - Postprandial abdominal pain or diarrhea
  - Mechanical obstruction or severe hypomotility
  - Malabsorption
  - Presence of high-output fistula

Parenteral Nutrition

Parenteral nutrition should be considered if **energy intake cannot**, or it is anticipated that it cannot be met by **enteral nutrition** (<50% of daily requirements) for >**7–10 days**.

Q. Discuss the indications, types and complications associated with total parenteral nutrition.

Central access: Total parenteral nutrition (TPN) both long, and short-term placement.

- The **infusion of hyperosmolar** (usually >1,500 mOsm/L) nutrient solutions requires a **large-bore, high-flow vessel** to minimize vessel irritation and damage.
- Percutaneous subclavian vein catheterization and peripherally inserted central venous catheterization (PICC) are the most commonly used techniques for **central parenteral nutrition (CPN)** access.
- The internal jugular, saphenous, and femoral veins are also used, although they are less desirable because of decreased patient comfort and difficulty in maintaining sterility.

---

*Determined by medical status, feeding route and volume, and nutritional goals.

- **Tunneled catheters** are preferred in patients who are likely to receive >8 weeks of TPN to reduce the risk of mechanical failure.
- **CPN macronutrient solutions:**
  - Crystalline amino acid solutions
  - Branched-chain amino acids for patients of hepatic encephalopathy, renal insufficiency
  - Glucose (dextrose) solutions
  - Lipid emulsions

Peripheral parenteral nutrition (PPN): Peripheral parenteral nutrition is often considered to have limited usefulness because of the high risk of thrombophlebitis.

Advantages and disadvantages of parenteral nutrition have been shown in ***Table 15.10.***

Indications for total parenteral nutrition have been shown in ***Box 15.8****. Complications of parenteral nutrition have been shown in* ***Table 15.11****.*

TABLE 15.10: Advantages and disadvantages of parenteral nutrition.

Advantages	*Disadvantages*
➢ Provides nutrients when <2–3 feet of small intestine remains ➢ Allows nutrition support when GI intolerance prevents oral or enteral support	➢ Economic impact ➢ Time-consuming ➢ Inconvenient ➢ Activities and work must be planned around feedings

Box 15.8: Indications of parenteral nutrition.

- Nonfunctioning GIT
- Nil per oral (NPO) >5 days
- GI fistula
- Acute pancreatitis
- Short bowel syndrome
- Malnutrition with >10–15% weight loss
- Nutritional needs not met; patient refuses food

Refeeding Syndrome

- **Definition:** Refeeding syndrome is a syndrome consisting of metabolic disturbances that occur as a result of reinstitution of nutrition to patients who are starved or severely malnourished.
- **Time of occurrence:** Usually occurs **within 4 days** of restarting nutritional support.

Mechanism

- When nutritional support is given to a starved or severely malnourished patient, there is a **rapid change from a catabolic to an anabolic state.**
- Administration of carbohydrates stimulates **release of insulin**. This causes cellular uptake of phosphate, potassium, and magnesium and may lead to significant falls in their levels in the serum. This results in electrolyte imbalance and can produce serious consequences (e.g., cardiac arrhythmias).
- **Clinical features**
  - Initial features may be **nonspecific**.
  - **Later:** Rhabdomyolysis, leukocyte dysfunction, respiratory and cardiac failure, hypotension, arrhythmias, seizures, coma, and sudden death.

Treatment of refeeding syndrome

- Start nutrition at **5–10 kcal/kg/day,** and **increase levels gradually**.
- Provide **thiamine, multivitamins and trace elements**.
- In thiamine-deficient patients, Wernicke's encephalopathy can be precipitated by refeeding with carbohydrates. This is prevented by providing thiamine before starting nutritional support.
- Restore the **circulatory volume**. Monitor fluid balance and clinical status.
- Replace **PO_4, K, and Mg.**

TABLE 15.11: Complications of parenteral nutrition.

	First 48 hours	*First 2 weeks*	*3 months onward*
Mechanical	➢ Malposition ➢ Hemothorax/pneumothorax ➢ Air embolism ➢ Blood loss ➢ Puncture of subclavian/carotid artery	➢ Catheter displacement ➢ Thrombosis ➢ Air embolism ➢ Occlusion	➢ Tear of catheter ➢ Catheter thrombosis ➢ Air embolism ➢ Blood loss
Metabolic/GI	➢ Fluid overload ➢ Hypoglycemia, hypophosphatemia, Hypokalemia, hypomagnesemia ➢ Refeeding syndrome	➢ Hypoglycemic coma ➢ Acid-base and electrolyte imbalance	➢ Deficiency of essential fatty acids, vitamins or trace element ➢ Metabolic bone disease ➢ Liver disease
Infectious		➢ Catheter-induced sepsis ➢ Exit site infection	➢ Tunnel infection ➢ Catheter-induced sepsis ➢ Exit site infection

PROTEIN–ENERGY MALNUTRITION

Q. IM23.2 Discuss and describe the causes and consequences of protein caloric malnutrition in the hospital.

Protein–energy malnutrition (**PEM**) **or protein–calorie malnutrition** includes marasmus, kwashiorkor and intermediate states of marasmus-kwashiorkor.

Marasmus

Q. Write a short note on marasmus.

- *Marasmus* is the childhood form of **starvation**.
- It develops **due to inadequate intake of protein and calories.**
- It is characterized by **emaciation** with apparent muscle wasting and loss of body fat.
- There is **no edema**.
- The hair is thin and dry.
- The marasmic child does not appear as apathetic or anorexic as with kwashiorkor.
- **Diarrhea** is frequent and there may be signs of infection.

Kwashiorkor

- Kwashiorkor develops due to an **inadequate protein intake with reasonable caloric** (energy) intake.
- *Kwashiorkor* occurs in a **young child displaced from breastfeeding by a new baby**.
- It may be **precipitated by infections** (e.g., measles, malaria, and diarrheal illnesses).
- Child appears **apathetic and lethargic with severe anorexia**.
- **Edema:** In kwashiorkor, marked protein deprivation causes **hypoalbuminemia** leading to **generalized or dependent edema.**
- **Skin lesions:** Children with kwashiorkor have characteristic *skin lesions*. This consists of alternating zones of hyperpigmentation, and hypopigmentation, producing **'flaky paint' appearance**.
- **Hair changes:** The hair is **dry and sparse**. There may be loss of color or alternating bands of pale and darker hair (**flag sign**).
- **Other features:** The other features that differentiate kwashiorkor from marasmus are:
    - Abdomen is distended due to **hepatomegaly** (presence of enlarged, fatty liver) and/or **ascites.**
    - Development of apathy, listlessness, and **loss of appetite**.
    - Likely presence of **vitamin deficiencies**.
    - Defects in immunity and secondary **infections.**

Treatment of PEM

- Provision of **protein and energy supplements**.
- Control of infection.
- The most common electrolyte abnormalities are hypokalemia, hypocalcemia, hypophosphatemia, and hypomagnesemia. Macronutrient repletion should be commenced within 48 hours.
- Supply macronutrients by dietary therapy. Milk-based formulas are the treatment of choice. After 1 week, 60 kcal/kg and 2 g/kg of protein for adults.

OBESITY

Q. IM14.1 Define and measure obesity as it relates to the Indian population.

- **Definition:** Obesity is defined as an accumulation of **excess body fat (adipose tissue)** that is of **sufficient magnitude to impair health.** Latin word 'obesus' meaning stout, fat, plump.
- **Measurement of obesity**
    - Body mass index—weight/height^2 in kg/m^2
    - Anthropometry—skinfold thickness
    - Densitometry—underwater weighing
    - CT/MRI imaging
    - Electrical impedance
- **Classification of overweight and obesity by BMI (Table 15.12).**

TABLE 15.12: Nutritional status based on the WHO and "Asian criteria" values.

Nutritional status	*WHO criteria BMI cut off*	*"Asian criteria" BMI cut off*
Underweight	<18.5	<18.5
Normal	18.5–24.9	18.5–22.9
Overweight	25–29.9	23–24.9
Pre-obese	–	25–29.9
Obese	>30	>30
Obese type-1 (obese)	30–40	30–40
Obese type-2 (morbid obese)	40.1–50	40.1–50
Obese type-3 (super obese)	>50	>50

TABLE 15.13: Etiology and risk factors of obesity.

Genetic aspects	***Environmental factors***
➢ Obesity is a **polygenic disorder**, with small contributions from a number of different genes. ➢ Single-gene (**monogenic forms**) disorders are rare and produce severe childhood obesity—mutations in the leptin gene and leptin receptor gene, mutations of *POMC* (pro-opiomelanocortin), *Mc4R* (melanocortin-4 receptor) *genes* ➢ A few **genetic conditions in which obesity** is a feature including the Prader–Willi and Laurence–Moon–Biedl syndromes	➢ **Food:** Many environmental factors can influence food intake ➢ Increased consumption of energy-dense foods, larger food portion size, and increased variety of food, increased availability, reduced cost and increased caloric beverages (soft drinks, juices) promote obesity ➢ **Physical activity:** (1) exercise (fitness and sports-related activities); (2) work-related physical activity; and (3) non-exercise, nonemployment (spontaneous) activity. ➢ Increased sedentary behavior, reduced activities of daily living and decreased physical activity promote obesity
Reversible causes of obesity and weight gain ➢ Minority of patients presenting with obesity have specific cause which can be identified and treated **(Table 15.14)**. ➢ Compared to idiopathic obesity, these patients have short history of marked weight gain	

- **Types of obesity according to body fat distribution:**
  The distribution of the stored fat is important in obesity and accordingly obesity is divided into:
  - **Central (abdominal, visceral, android or apple-shaped) obesity**:
    - This type of obesity shows **increased accumulation of fat in the trunk** and in the **abdominal cavity** (in the mesentery and around viscera).
    - It is associated with a **greater risk** for several diseases (e.g., type 2 diabetes, the metabolic syndrome, and cardiovascular disease) than generalized obesity.
    - **Increased Waist: Hip ratio—**>0.9 in females, >1 in males is abnormal.
    - Hypothesis—intra-abdominal adipocytes are more lipolytically active than others—release free fatty acids into portal circulation—cause adverse metabolic reactions, especially on the liver.
  - **Generalized ('gynoid' or 'pear-shaped') obesity:** This type is characterized by excess accumulation of **fat diffusely in the subcutaneous tissue.**

Etiology (Table 15.13)

Q. IM14.2 Describe and discuss the etiology of obesity including modifiable and nonmodifiable risk factors and secondary causes.

- Accumulation of fat in obesity can be considered by the result of **caloric imbalance** between the energy consumption (**intake** of calories) in the diet and **energy expenditur**e through exercise and bodily functions.
- However, the pathogenesis of obesity is complex and incompletely known.

Table 15.14 shows Potentially reversible causes of obesity and weight gain.

Q. IM 14.3 Describe and discuss the monogenic and polygenic forms of obesity.

Monogenic and Polygenic Obesity

See **Table 15.15**

Adipocyte and Adipose Tissue (Figs. 15.10 and 15.11)

- Adipose tissue consists of adipocytes and stromal/vascular component (preadipocytes, macrophages, fibroblasts, collagen tissue).
- Adipose mass increases by:
  - Enlargement of adipose cells through lipid deposition

TABLE 15.14: Potentially reversible causes of obesity and weight gain.

Endocrine factors	
➢ Hypothyroidism ➢ Cushing's syndrome ➢ Insulinoma	➢ Stein–Leventhal syndrome ➢ Hypothalamic damage (e.g., due to trauma, tumor)
Drug induced	
➢ **Psychiatric and neurologic medications:** Atypical antipsychotics (e.g., olanzapine) pizotifen, sodium valproate, flunarizine ➢ **Steroid hormones:** Progestational steroids, corticosteroids, hormonal contraceptives	➢ **Antidiabetic agents:** insulin (most forms), sulfonylureas, thiazolidinediones ➢ **Antihypertensive agents:** α- and β-adrenergic receptor blockers

TABLE 15.15: Features of monogenic and polygenic obesity.

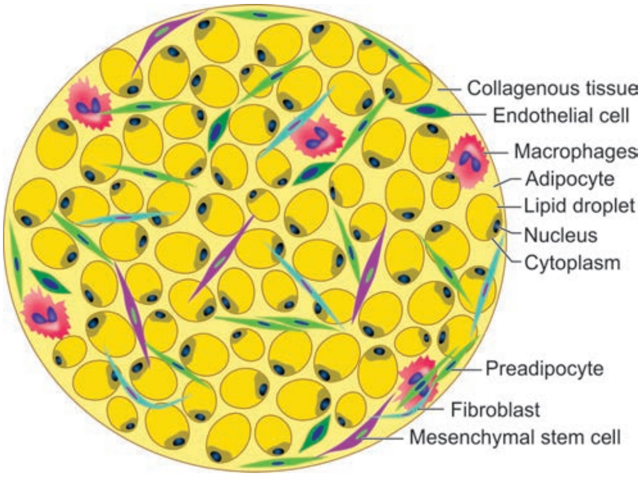
Feature	*Monogenic obesity*	*Polygenic obesity*
Genes	➢ LEP (Leptin) ➢ LEPR (Leptin receptor) ➢ POMC (Pro-opiomelanocortin) ➢ PCSK1 (Prohormone convertase 1/3) ➢ MC4R (Melanocortin 4 receptor) ➢ SIM1 (Single-Minded Homolog 1)	➢ PPARG (Peroxixome proliferator-activator receptor γ) ➢ Adiponectin (ADIPOQ) ➢ FTO (Fat-mass and Obesity associated gene) ➢ LEP (Leptin)
Mutation	➢ Autosomal loss-of-function mutation, usually dominant or co-dominant ➢ More severe in homozygous individuals	
Features	➢ High BMI ➢ Compulsive hyperphagia ➢ Endocrinal abnormalities ➢ Developmental delay	Influenced by environmental external factors like exposure to physical, chemical or biological agents, diet

- Increase in number of adipocytes
- Increase in number of infiltrating macrophages.

Pathogenesis (Fig. 15.12)

Peripheral Afferent System

- Peripheral afferent system can be further subdivided into **peripheral appetite suppressing signals** and **peripheral appetite stimulant signals.**
- *Peripheral appetite suppressing signals*
  - **Leptin (Greek term leptos, meaning 'thin'):** Leptin is a **hormone secreted by fat cells** and it stimulates POMC (pro-opiomelanocortin)/CART (cocaine and amphetamine-regulated transcript) pathway **(Fig. 15.13)** and inhibits NPY/AgRP pathway causing **appetite** to be **suppressed** (anorexigenic). Increased leptin **stimulates physical**



Collagenous tissue
Endothelial cell
Macrophages
Adipocyte
Lipid droplet
Nucleus
Cytoplasm
Preadipocyte
Fibroblast
Mesenchymal stem cell

FIG. 15.10: Adipose tissue.

				White adipose tissue	***Brown adipose tissue***	***Beige adipose tissue***
Localization	➢ Subcutaneous ➢ Intra-abdominal ➢ Epicardial ➢ Gonadal	➢ Interscapular ➢ Paravertebral ➢ Perirenal ➢ Cervical ➢ Supraclavicular	Emerges in white adipose tissue depots with appropriate stimuli
Morphology	Spherical	Elliptical and smaller than white	Spherical
Cell composition	➢ Single lipid droplet ➢ Few mitochondria ➢ Flattened peripheral nucleus ➢ Little endoplasmic reticulum	➢ Multiple small lipid droplets ➢ Large number of mitochondria ➢ Oval central nucleus	➢ Unilocular morphology but small lipid droplets after stimulation ➢ Mitochondria appear after stimulation
Function	Storing energy	Expending energy and heat production (nonshivering thermogenesis)	Thermogenic potential
Uncoupling protein	Undetectable	Positive	Positive after stimulation

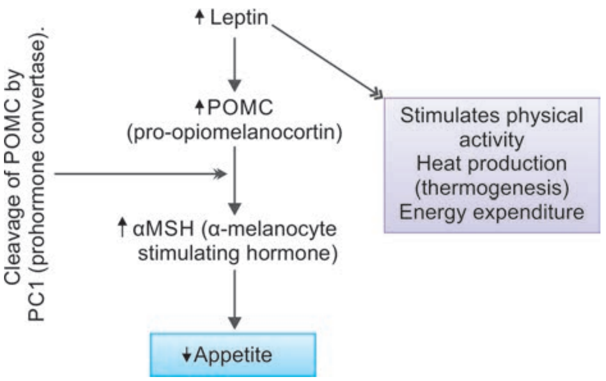
Energy balance
Peripheral efferent system

FIG. 15.12: Regulation of energy balance. Peripheral afferent system (appetite suppressing and stimulating signals) influences the activity of the hypothalamus, which is the central regulator of appetite and satiety. Signals from hypothalamus in turn act on peripheral efferent system (food intake and energy expenditure).

  activity, heat **production** (thermogenesis), and **energy expenditure**.
  - **Adiponectin:** It is a hormone (**fat-burning molecule)** and the 'guardian angel against obesity,' and is produced mainly by fat cells (adipocytes). Its levels are lower in obese.
  - **Resistin**: Primarily produced by macrophages and not fat cells. It **causes insulin resistance.**
  - **Gut hormones:** These include peptide YY (PYY), pancreatic polypeptide, insulin, and amylin.
    - **Insulin:** It is **secreted by cells of the pancreas** and acts centrally to **activate the appetite suppressing pathway**.
    - **Peptide YY:** It is **secreted by the endocrine cells** (L cells) in the ileum and colon. It **reduces appetite**. Other peripheral **appetite suppressing** signals include glucagon like peptide 1 (**GLP1**) and oxyntomodulin.
    - **Amylin:** It is a peptide secreted with insulin from pancreatic β-cells.



↑Leptin
↑POMC (pro-opiomelanocortin)

↓Appetite
Stimulates physical activity
Heat production (thermogenesis)
Energy expenditure

FIG. 15.13: Actions of leptin.

- *Peripheral appetite-stimulating signals*
  - **Gut hormones:**
    - **Ghrelin:** It is produced by the **oxyntic cells of the fundus of the stomach** and in the **arcuate nucleus of the hypothalamus**. Ghrelin **increases food intake** (orexigenic effect) and **stimulates appetite** by activating the central appetite stimulating NPY/AgRP pathway.
    - **Obestatin:** It is a peptide produced by the **same gene that encodes ghrelin**. It counteracts the **increase in food intake induced by ghrelin**.
  - **Retinol-binding protein 4 (RBP4):** Secreted by fat cells. Its actions counteract with those of insulin. Raised levels of RBP4 found in type 2 diabetes mellitus.

Central Processing (Table 15.16)

The arcuate nucleus of the hypothalamus processes and integrates neurohumoral peripheral afferent signals and generates efferent signals. It consists of:

- *Central appetite-suppressing (anorexigenic pathway or leptin melanocortin pathway):* In this pathway, **POMC/CART neurons enhance energy expenditure** and weight loss through the production of the anorexigenic (suppresses appetite) neuropeptides mainly α-MSH (α-melanocyte-stimulating hormone) by cleavage of POMC by PC1 (prohormone convertase).

TABLE 15.16: Examples of central nervous system regulators of energy balance.

Central anabolic (increased intake) regulators	***Central catabolic (decreased intake) regulators***
Neuropeptide Y	α-Melanocyte-stimulating hormone
Agouti-related protein	Corticotropin-releasing hormone
Melanin-concentrating hormone	Thyrotropin-releasing hormone
Hypocretins and orexins	Cocaine- and amphetamine-regulated transcript (CART)

- *Central appetite-stimulating (orexigenic) pathway:* It consists of:
  - NPY (neuropeptide Y)/AgRP (agouti-related peptide) containing neurons promote food intake (orexigenic effect) and weight gain, through the activation of Y1/5 receptors in secondary neurons.
  - Secondary neurons in turn release factors such as melanin-concentrating hormone (MCH) and orexin, which stimulate appetite. This pathway also decreases energy expenditure.

Peripheral Efferent System

- It is organized into two pathways namely anabolic and catabolic that control food intake and energy expenditure, respectively.
- **Energy intake (food intake)**
  - **Food:** The increase in obesity can be related to the type of food consumed (i.e., food-containing sugar and fat) and also psychological factors.
  - **Control of appetite:** Signals may affect different aspects of eating behavior. For example:
    - **Ghrelin** (peptide produced by the stomach) **increases hunger but does not affect satiation or satiety.**

  - **Cholecystokinin causes satiation**, but has **no effect on satiety**.
  - **Leptin acts on multiple pathways**, its deficiency causes increased hunger and reduced satiation and satiety.
- Following a meal, substances such as cholecystokinin (CCK), bombesin, and glucagon–like peptide-1 (GLP-1) are released from the small intestine, and glucagon and insulin from the pancreas. These hormones are involved in the control of satiety. The control of appetite is extremely complex. Many transmitters in the central nervous system affect appetite:
  - **Appetite inhibitors:** Dopamine, serotonin, γ-aminobutyric acid
  - **Appetite stimulators:** Opioids

- **Energy expenditure**

  It can be divided into resting (or basal) metabolic rate, the thermic effect of food, and physical activity energy expenditure.
  - **Resting basal metabolic rate (BMR):** BMR is the energy expenditure and accounts for about 70% of daily energy expenditure, whereas active physical activity contributes to 5–10% of energy expenditure.
  - **Thermic effect of food (thermogenesis):** About 10% of ingested energy is spent in the process of digestion, absorption, and metabolism of nutrients irrespective of physical activity. This is called as dietary-induced thermogenesis which is lower in obese individuals.
  - **Physical activity:** Obese individuals tend to spend more energy during physical activity as they have a larger mass to move.

Theory of Body Weight 'Set Point' in Hypothalamus (Fig. 15.14)

Pathologic Consequences of Obesity (Complications of Obesity)

Q. IM14.5 Describe and discuss the natural history of obesity and its complications.

Morbidity and mortality: Obesity is associated with an **increase** in mortality and morbidity. Obese individuals are at risk of early death, mainly from diabetes, coronary heart disease, and cerebrovascular disease.

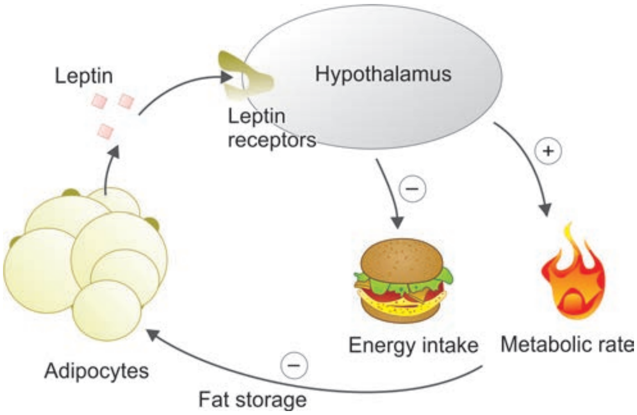

FIG. 15.14: Lipostat/adipostat—body weight "set point" in hypothalamus.

Metabolic Complications of Obesity

- Central obesity or upper body fat distribution is associated with increased concentration of FFA (free-fatty acid), which can produce several metabolic complications of obesity.
- **Insulin resistance and type 2 diabetes mellitus**
  - Insulin resistance is the decrease/failure of response of target (peripheral) tissues to insulin action.
  - Insulin resistance can develop in obesity and may produce type 2 diabetes mellitus.
  - **Central/upper body/visceral obesity** is found in >80% of patients with **type 2 diabetes.**
  - **Causes of insulin resistance in obesity:**
    - **Obese individuals** have **excess** circulating **FFAs** and there is an **inverse correlation between fasting plasma FFAs and insulin sensitivity**. Central obesity is associated with **insulin resistance**. **Excess intracellular FFAs increase gluconeogenesis**.
    - **Adipokines: Adipose tissue** acts as a functional endocrine organ and **secretes variety of proteins** into the systemic circulation, which are **termed adipokines** (or adipose cytokines). **In obesity, adiponectin (one of the adipokines) levels are reduced,** which contributes to insulin resistance.
  - **Consequences of insulin resistance (Box 15.9).**

Box 15.9: Consequences of insulin resistance.

- **Muscle:** Hyperglycemia and diabetes mellitus
- **Kidneys:** Salt retention and hypertension
- **Ovaries:** Increase testosterone and polycystic ovary syndrome (PCOS)
- **Heart:** Increase plasminogen activator inhibitor-1 (PAI-1) and acute coronary syndrome
- **Cancers:** Colon, prostate, breast
- **Sympathetic system:** Increased cytokines and blood pressure

- **Dyslipidemia**
  - Upper body obesity and type 2 diabetes mellitus are associated with an atherogenic lipid profile. Dyslipidemia includes **increased triglycerides, increased low-density lipoprotein (LDL) cholesterol with very low-density lipoprotein (VLDL) cholesterol**, decreased **high-density lipoprotein (HDL**) cholesterol, and decreased levels of the vascular protective adipokine adiponectin.
  - Dyslipidemia increases the risk of cardiovascular diseases (**atherosclerosis, cardiomyopathy**) in the metabolic syndrome **(Fig. 15.15)**.
- **Endocrine manifestations of obesity**
  - Reproductive disorders associated with obesity are listed in **Table 15.17**.
- **Mechanical complications of obesity**

Osteoarthritis: Extremity degenerative joint disease (osteoarthritis) and also gout.

- **Venous stasis/varicose veins**.
- **Acanthosis nigricans:** Reflects the severity of underlying insulin resistance.
- **Increased friability of skin:** It may be seen especially in skinfolds, thereby increasing the risk of fungal and yeast infections.
- **Urinary incontinence**.
- **Pulmonary disease**
  - These include reduced chest wall compliance, increased work of breathing, increased minute ventilation (due to increased metabolic rate), and decreased functional residual capacity and expiratory reserve volume.
  - **Obstructive sleep apnea:** Sleep apnea is common in patients with severe obesity. Sleep apnea can be obstructive (most common), central, or mixed and is often associated with an increased risk of hypertension, right heart failure and sudden death. Obesity hypoventilation syndrome is also known as **Pickwickian syndrome**.
  - **Obesity and asthma:** Reduced TLC (total lung capacity), reduced RV (residual volume) and FRC (functional residual capacity).
- **Obesity and cancer (Table 15.18)**
  - Obesity is the biggest preventable cause of cancer after smoking.
  - Accounts for 14% of cancer deaths in men and 20% in women.
- **Gastrointestinal disorders:** Following are more prevalent in obese patients:
  - **Gastroesophageal reflux disease**
  - **Gallstones:** Obesity is associated with increased secretion of cholesterol in the bile, supersaturation of bile, and a higher incidence of gallstones, especially cholesterol gallstones.
  - **Fatty liver (steatosis) and nonalcoholic steatohepatitis: Nonalcoholic fatty liver disease (NAFLD)** can progress to hepatic cirrhosis and rarely to hepatocellular carcinoma.
- **Obesity and retinal disease**
  - Overweight diabetics are twice more likely to develop retinopathy than nonobese.
  - Waist to hip ratio was only second to glycemic control in its importance in preventing retinopathy in studies.
  - Conditions and complications associated with obesity are summarized in **Table 15.19**.

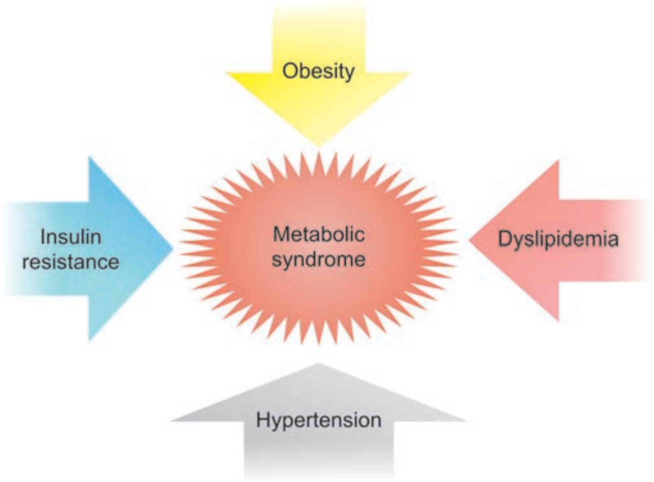

FIG. 15.15: Obesity and metabolic syndrome.

TABLE 15.17: Endocrine manifestations of obesity.

Men	*Women*
➢ Plasma testosterone and SHBG are reduced ➢ Increase estrogen ➢ Gynecomastia seen ➢ Secondary sexual characters preserved	➢ Increased androgen ➢ Decrease SHBG ➢ PCOS ➢ Not only fertility but their chances of IVF success reduce

(SHBG: Sex hormone-binding globulin; PCOS: Polycystic ovary syndrome)

TABLE 15.18: Obesity and related cancers.

Males	*Females*
Esophagus	Gallbladder
Colon	Bile ducts
Rectum	Breasts
Pancreas	Endometrium
Liver	Cervix
Prostate	Ovaries

TABLE 15.19: Conditions and complications associated with obesity.

Risk factors/system involved	*Outcomes*
Metabolic syndrome	
Type 2 diabetes	Coronary heart disease, ischemic heart disease
Hypertension	Stroke
Hyperlipidemia	Diabetes complications
Cardiovascular	Heart failure
Gastrointestinal	Gastroesophageal reflux disease, hiatus hernia
Hepatobiliary	Liver fat accumulation, nonalcoholic steatohepatitis, cirrhosis, gallstones
Pulmonary disease	Exertional dyspnea, breathlessness
Restricted ventilation Obesity hypoventilation syndrome (Pickwickian syndrome)	Obstructive sleep apnea
Mechanical effects of weight **Endocrine manifestations** (Increased peripheral steroid interconversion in adipose tissue)	➢ Urinary incontinence, osteoarthritis of knees and hips, varicose veins, back strain ➢ Menstrual abnormalities ➢ Hormone-dependent cancers (breast, uterus) ➢ Polycystic ovarian syndrome (infertility, hirsutism)
Increased morbidity and mortality	
Psychological problems	Lack self-confidence, depression, more physical and sexual abuse, lack of attention, low education, and low self-esteem
Others	Accident-proneness, socioeconomic disadvantage (lower income, less likely to be promoted), postoperative problems, increased cancer risk (e.g., colorectal cancer), skin infections (groin and submammary candidiasis; hidradenitis)

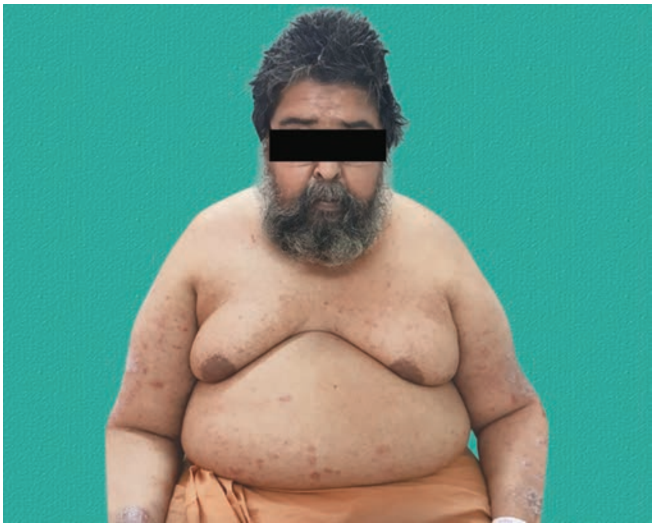
INVESTIGATIONS

Q. IM14.10 Describe the indications and interpret the results of tests for secondary causes of obesity.

Aims of Investigation

- Confirm diagnosis and rule out differentials
- Find underlying etiology
- Complications and comorbidities

- ➢ BMI = Wt in Kg/(Ht)^2 in m^2
- ➢ Waist circumference
- ➢ Sagittal abdominal diameter
- ➢ Caliper-derived measurements of skin-fold thickness
- ➢ Bioelectrical impedance analysis
- ➢ Underwater weighing
- ➢ Ultrasonography: NAFLD, gallstones, ovarian cysts
- ➢ Dual-energy radiographic absorptiometry (DEXA)
- ➢ Abdomen CT scan (at L4/L5)
- ➢ Abdomen MRI
- ➢ Lipid profile (FLP)
- ➢ Liver function test (LFT)
- ➢ Renal function test (RFT)
- ➢ Uric acid
- ➢ FBG/HbA1c
- ➢ ECG
- ➢ Echocardiography
- ➢ Sleep studies
- ➢ C-peptide and Insulin studies
- ➢ Brain MR
- ➢ Genetic studies
- ➢ GH and IGF-1 assays
- ➢ Plasma leptin



[redacted]

FIG. 15.16: Appearance of a patient with morbid obesity.

Aims of assessing of obesity are to:

1. **Evaluate and quantify severity of obesity:** Severity of obesity can be quantified using the BMI.
2. **Exclude an underlying cause**
3. **Identify complications**
4. **Prepare a management plan (***refer* **Table 15.12)**

Appearance of a patient with morbid obesity is shown in **Figure 15.16**.

Q. 14.13 Describe and enumerate the indications, pharmacology, and side effects of pharmacotherapy for obesity.

Management

- **Goal:**
  - Initially to reduce weight by about 10% from baseline
  - Reduce weight of about 0.5–1 kg/week for 6 months.

- **Lifestyle modification diet (Table 15.20)**
  - Low calorie diet, low in saturated fats, low density foods, normal protein intake and increased fibers in diet.
  - 1,000 kcal deficit produces 1 kg weight loss per week. No matter what the calorie intake is the constituents remain in same proportion (i.e., carbohydrates 55%, fat 30%, and protein 15%).
  - **Total fasting: Not recommended**. There is diuresis, natriuresis, and all deficiencies.
  - *Refeeding syndrome:* Severe and potentially fatal electrolyte, fluid and metabolic abnormalities when feeding is resumed.
  - **Physical activity:** Regular physical activity enables to maintain loss of weight. Has to be done under supervision. Moderate exercise to be done for 30–45 minutes and 3–5 days/week.
  - **Behavioral modification:** (1) Useful as adjunct to diet and physical exercise; (2) Patient often needs motivation to lose weight.

TABLE 15.20: Types of diet in the treatment of obesity.

Fixed energy diet	*Low-calorie diet*	*Very low-calorie diet (VLCD)*
➢ 1,200–1,800 kcal ➢ Intake is limited by controlling portion sizes, menu choice and composition ➢ Minimal self-monitoring ➢ Lack of compliance to this rigid pattern	➢ 800–1,000 kcal ➢ Applicable to most of the patients ➢ Fewer restrictions than VLCD ➢ Supplementation of vitamins and minerals ➢ Reduction of 6–7 kg observed over a year	➢ 400–600 kcal ➢ Even below one's basal metabolic rate ➢ Used for period of 1–2 months under medical supervision ➢ 45–70% protein, 30–50% carbohydrates, and 2 g fat ➢ Supplementation of vitamins, minerals, and trace elements ➢ Greater weight loss compared to restrictive diets

- **Drug therapy (pharmacotherapy):** Lifestyle modification should be considered before starting drug therapy.
  - *Centrally acting drugs*
    - **Sibutramine**
      - ❑ **Mechanism of action:** Centrally acting, monoamine reuptake inhibitor (primarily serotonin and norepinephrine). By sympathetic stimulation, it prevents decrease in BMR. It reduces appetite.
      - ❑ **Dose:** 10–15 mg once daily.
      - ❑ **Side effects:** Hypertension, tachycardia, sweating, dizziness, and headache.
      - ❑ **Contraindications:** Coronary artery disease, cardiac arrhythmias, uncontrolled hypertension.
    - **Rimonabant**
      - ❑ **Mechanism of action:** Endocannabinoid 1 receptor blocker. It has both central and peripheral actions and reduces weight and weight-related metabolic factors.
      - ❑ **FDA approval:** BANNED
      - ❑ **Side effects:** Depression, anxiety, suicidal tendencies.
  - *Peripherally acting drugs*
    - **Orlistat**
      - ❑ **Mechanism of action:** Nonsystemic reversible inhibitor of gastric and pancreatic lipases by forming a covalent bond with serine residue. It acts on stomach and intestine.
      - ❑ **Dose:** 120 mg BD or TID with meals.
      - ❑ **FDA approval:** For adults and adolescents as well as children.
      - ❑ **Side effects:** Flatulence, defecation increases, oily evacuation, rectal leakage, steatorrhea.
    - **Olestra:** Olestra is synthesized using a sucrose molecule, which can support from 6 to 8 fatty acid chains arranged radially like an octopus. Too large to move through the intestinal wall and be absorbed. Same taste and mouth feel as fat. Approval as a food additive up to 35% replacement of fats in home cooking and 75% in commercial uses.
  - **Others:**
    - **Phentermine:** Amphetamine like drug, acts centrally to reduce appetite. It has low addictive potential, modest efficacy and CVS side effects.
    - **Metformin:** Decreases appetite and thereby reduces weight. Since most DM 2 patients are obese, this is a good choice in DM 2.
    - **Tesofensine (TE)** is a norepinephrine, dopamine, and serotonin reuptake inhibitor. Primarily used as an appetite suppressant.
    - **Betahistine:** Stimulates the histamine-1 receptor and reduces the craving not only for food in general but for fatty foods in particular. Not approved by FDA.
    - **Amylin (pramlintide):** Part of the endocrine pancreas and contributes to glycemic control. Functions as a synergistic partner to insulin.
    - **Liraglutide,** a GLP-1 agonist (1.8 or 3 mg daily), is an option for overweight or obese patients.
    - **Lorcaserin,** serotonin agonist approved by FDA
    - **Combination therapy:**
      - ❑ Phentermine-topiramate
      - ❑ Bupropion-naltrexone

- **Liposuction:** It is the removal of large amounts of fat by suction (liposuction). It does not deal with the underlying cause and weight regain frequently occurs. There is no reduction in cardiovascular risk factors with the procedure.
- *Others:*
  - Electrical stimulation (vagal blockade) systems
  - Hydrogels**: Hydrogels are orally administered products, taken twice daily before meals, which expand in the stomach and intestines to create a sensation of satiety. They are not systemically absorbed, and are eliminated through the** feces.
  - Dietary supplements: Although over-the-counter dietary supplements are widely used by individuals attempting to lose weight—like ephedra, green tea, chromium, chitosan, and guar gum. These are not recommended and are inadequate and unsafe methods to lose weight.

Q. IM14.14 Describe and enumerate the indications and side effects of bariatric surgery.

Bariatric Surgery

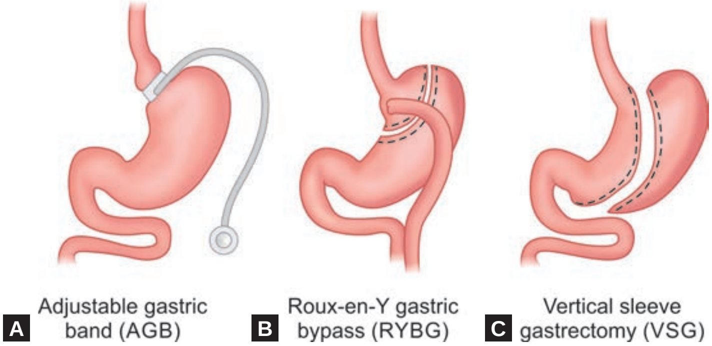
- **Indications:**
  - **BMI ≥40 kg/m^2** without comorbid illness **(Table 15.21)**
  - BMI 35.0–39.9 kg/m^2 with at least one serious comorbidity like:
    - Type 2 diabetes
    - Obstructive sleep apnea (OSA)
    - Hypertension
    - Hyperlipidemia
    - Obesity hypoventilation syndrome (OHS)
    - Pickwickian syndrome (combination of OSA and OHS)
    - Nonalcoholic fatty liver disease
    - Nonalcoholic steatohepatitis (NASH)
    - Pseudotumor cerebri
    - Gastroesophageal reflux disease
    - Asthma
    - Venous stasis disease
    - Severe urinary incontinence
    - Debilitating arthritis
    - Impaired quality of life
    - Disqualification from other surgeries as a result of obesity (i.e., surgeries for osteoarthritic disease, ventral hernias, or stress incontinence)
  - **BMI between 30.0–34.9 kg/m^2** and one of the following comorbid conditions like:
    - Uncontrollable type 2 diabetes
    - Metabolic syndrome

TABLE 15.21: Obesity—treatment according to BMI category (kg/m^2) for Asian Indians.

Treatment	≥23	≥25	≥27.5	≥32.5	≥37.5
Diet, exercise, behavior	+	+	+	+	+
Pharmacotherapy		With comorbidities	+	+	+
Bariatric surgery				With comorbidities	+

- **Contraindications:**
  - Untreated major depression or psychosis
  - Uncontrolled and untreated eating disorders (e.g., bulimia)
  - Drug and alcohol abuse
  - Severe cardiac disease, in which anesthesia may be dangerous and contraindicated
  - Severe coagulopathy
  - Compliance issues with long-term nutritional replacement (e.g., vitamins)
- **Bariatric surgical techniques:** Divided into three groups:

  Various surgical options for the treatment of obesity are shown in **Figures 15.17A to C.**
  1. **Malabsorptive procedures:** Induce decreased absorption of nutrients by shortening the functional length of the small intestine (e.g., biliopancreatic diversion and Roux-en-Y gastric bypass). These



A Adjustable gastric band (AGB) B Roux-en-Y gastric bypass (RYBG) C Vertical sleeve gastrectomy (VSG)

FIGS. 15.17A TO C: Various surgical options for the treatment of obesity.

procedures cause deficiency of nutrients, malnutrition and in some cases, anastomotic leaks and the dumping syndrome (e.g., with the duodenal switch).

2. **Restrictive procedures:** Reduce the storage capacity of the stomach and as a result early satiety arises, leading to a decreased caloric intake (e.g., adjustable gastric banding, vertical banded gastroplasty and sleeve gastroplasty).
3. **Restrictive plus malabsorptive procedures** (e.g., duodenal switch, Roux-en-Y gastric bypass, intragastric balloon).

- **Complications of the procedure:**
  - **During the procedure:**
    - Hemorrhage
    - Infections
    - Gastrointestinal leaks
    - Anesthesia-related complications
  - **Postoperative:**
    - Bowel obstruction
    - Dumping syndrome
    - Gallstones
    - Hernias
    - Malnutrition, hypoglycemia
    - Gastroesophageal reflux disease
    - Repeat surgery may be required.

CHAPTER 16

Neurology

INTRODUCTION AND SYMPTOMATOLOGY

Weakness and Paralysis

Categories (Flowchart 16.1 and Fig. 16.1)

- **Upper motor neurons:** They consist of corticospinal interneurons which arise from the motor cortex and descend to the spinal cord where they activate the lower motor neurons (anterior horn cells) through synapses.
- **Lower motor neurons:** The term "motor neuron" is usually used only to the efferent neurons that actually innervate muscles (the lower motor neurons). A motor neuron consists of nerve cell (neuron) which is located in the anterior horn cell of the spinal cord and its fibers (axon) project outside the spinal cord to directly or indirectly control effector organs, mainly muscles and glands. Motor neuron axons are efferent nerve fibers and carry signals from the spinal cord to the effectors to produce effects.

Signs of Upper and Lower Motor Neuron Disease

Q. List the differences between upper motor neuron disease and lower motor neuron disease.

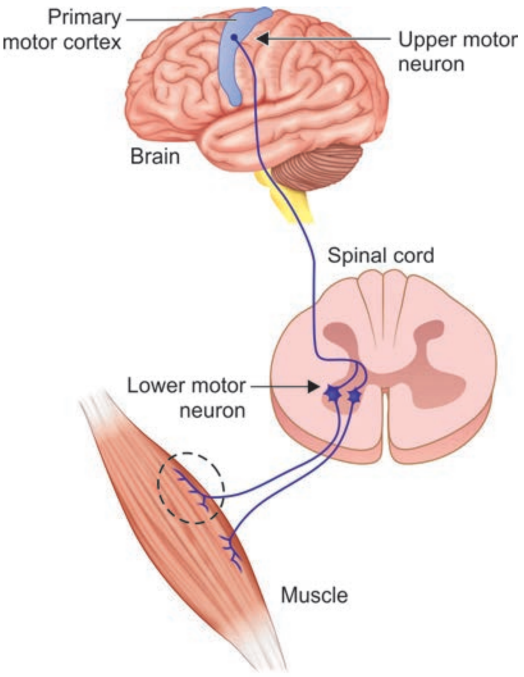
The differences between upper motor neuron disease and lower motor neuron disease are listed in **Table 16.1**.

Tone

- Muscle tone is a partial state of contraction of a skeletal muscle to maintain its optimal length during resting condition, even when a

TABLE 16.1: Signs of upper and lower motor neuron disease.

Sign	*Upper motor neuron*	*Lower motor neuron*
Atrophy	None (rarely disuse atrophy)	Severe wasting
Muscles affected	Group of muscles	Single
Fasciculations	None	Common
Tone	Hypertonia—rigidity/spasticity	Decreased (hypotonia)
Distribution of weakness	Distal predominant/regional	Predominantly proximal (except neuropathy)/segmental
Tendon reflexes	Exaggerated/hyperactive	Hypoactive/lost
Babinski's sign	Present	Absent
Flexor spasms, clonus	Present	Absent



Primary motor cortex
Upper motor neuron
Brain
Spinal cord
Lower motor neuron
Muscle

FIG. 16.1: Upper and lower motor neurons—a two-neuron circuit.

force is applied to elongate the muscle. It is accomplished by the asynchronous discharge of nervous impulse in the motor neurons in the anterior gray horn of the spinal cord.

- Clinically, it may be defined as the resistance that is encountered when the joint of relaxed muscle is moved passively.
- **Increased tone:** Associated with disease of upper motor neurons due to loss of inhibition of γ-motor neurons above the site of lesion.

Q. List the causes of hypotonia.

Causes of hypotonia is listed in **Box 16.1**.

Q. Enumerate the differences between spasticity and rigidity.

The differences between spasticity and rigidity are listed in **Table 16.2**.

Box 16.1: Causes of hypotonia.

- **Lesions of the motor side of the reflex arc:** Poliomyelitis, polyneuritis, peripheral nerve injuries
- **Lesions of the sensory side of the reflex arc:** Tabes dorsalis, herpes zoster, carcinomatous neuropathy
- **Combined motor and sensory lesion:** Syringomyelia, cord or root compression, gross cord destruction
- Lesions of the muscle (myopathies), neuromuscular junction (NMJ) (myasthenia)
- State of neuronal shock in upper motor neuron lesion
- Cerebellar lesions
- Chorea
- Periodic paralysis
- Rapid eye movement (REM) sleep
- Benzodiazepine overdose, neuromuscular blockers

TABLE 16.2: Differences between spasticity and rigidity.

	Spasticity	***Rigidity***
Lesion	Pyramidal tract lesion	Extrapyramidal tract lesion
Tone	Tone is more in the antigravity group of muscles than in the gravity assisted group of muscles	Tone is equally raised in the gravity assisted and antigravity group of muscles
Character	Clasp knife type of spasticity	Lead pipe or cogwheel type of rigidity
Relation to velocity	Velocity dependent, better appreciated when passive movement of the joint is carried out rapidly	Rigidity is not velocity dependent
Abdominal reflexes	Lost	Preserved
Plantar reflex	Plantar is extensor	Plantar is flexor
Deep tendon reflexes	Brisk or exaggerated	Normal or decreased
Clonus	May be associated sustained clonus	Clonus is absent
Features in limbs	The limb does tend to return toward a particular fixed posture or extreme joint angle	The limb does not tend to return toward a particular fixed posture or extreme joint angle
Reason	Increased gamma-motor activity	Increased alpha- and gamma-motor activity

Other causes of hypertonia: Tetanus, seizure (tonic phase), tetany, **catatonia, paratonia *(gegenhalten, mitgehen).***

Fasciculation and Fibrillation

Q. What is fasciculation and fibrillation?

When a motor unit (group of muscle fibers) becomes diseased, especially in anterior horn cell diseases, it may discharge spontaneously, producing **fasciculations** that may be seen or felt clinically or recorded by electromyography (EMG). Fasciculations are visible, fine and fast, sometimes vermicular contractions of fine muscle fibers that occur spontaneously and intermittently.

When motor neurons or their axons degenerate, the denervated muscle fibers also may discharge spontaneously. These single muscle fiber discharges, or **fibrillation** potentials, cannot be seen or felt but can be recorded with EMG.

Causes of fasciculation: Amyotrophic lateral sclerosis, progressive spinal muscular atrophy, post-polio syndrome, hyperthyroidism, organophosphorus poisoning, drugs (e.g., atropine, lithium), mercury, benign fasciculation.

Myotonia

Q. What is myotonia?

- Myotonia is characterized by continued, involuntary muscle contraction even after cessation of voluntary effort (i.e., muscle contraction continues beyond the period of time required for a particular movement to be made and there is failure of normal muscle relaxation).
- It is best seen in the face and hand muscle. When the patient is asked to smile and then relax his facial muscle, a delay in relaxation of the muscle is noted and the smile remains fixed for a longer duration (transverse smile). Similarly, when the patient is asked to grip the examiner's fingers and then let go immediately, a delay in the relaxation of the grip is noted.

- **Myokymia** is a vermicular or continuous rippling movement of a group of muscle fibers that can be seen in neuropathies [Guillain–Barré syndrome (GBS)], plexopathies, and Isaac's syndrome.

Causes of myotonia

See **Box 16.2.**

Box 16.2: Causes of myotonia.

- Myotonic dystrophy type 1
- Myotonic dystrophy type 2/proximal myotonic myopathy
- Myotonia congenita
- Paramyotonia congenita
- Hyperkalemic periodic paralysis

Ataxia

Q. Write a short note on causes of ataxia.

Ataxia is a disorder characterized unsteadiness and impaired coordination of regulating body posture and the rate, range, force, and direction of movement. Types of ataxia are listed in **Box 16.3**.

Box 16.3: Types of ataxia.

- **Cerebellar:** Vasculitis, multiple sclerosis, infection bleeding, infarction, tumors, direct injury, toxins (e.g., alcohol), genetic disorders
- **Sensory:** Posterior column diseases, large fiber neuropathy
- Optic
- Vestibular
- Frontal lobe ataxia (Bruns ataxia)
- Mixed
- Psychogenic
- Pseudoataxia

Reflexes

Plantar Response/Reflex

Q. Write a short note on plantar reflex and extensor plantar reflex/ Babinski's sign.

Plantar response/reflex is nociceptive, superficial reflex. Its segmental innervation is S1 segment of the spinal cord. It was first described by Babinski.

Technique

- Position the patient in supine with hip and knee extended.
- Fix the ankle joint by holding it and stroke (gentle but firm pressure) the outer aspect of sole with a blunt point (tip of a key). The stroke is directed forward and then curves inward along the metatarsophalangeal joints from the little to the big toe and stopped short of the base of great toe (root value S1).

Interpretation

Normal response is great toe will flex at the metatarsophalangeal joint accompanied by flexion of other toes. Normal response should not be termed "negative Babinski's sign".

Abnormal responses

- **Absent:** No response is seen. Plantar response/reflex may be absent when there is loss of sensation of the sole (L5–S1), thick sole, paralysis of the extensor hallucis, and lesions of reflex arc.
- **Extensor:** Extension (dorsiflexion) of the great toe with or without fanning of others toes (abduction) is known as **Babinski's sign (mediated by L5)**. Fanning of toes without great toe extension has no significance. When fully developed it is accompanied by dorsiflexion of ankle, flexion of hip and knee joint, and slight abduction of thigh with contraction of the tensor fascia lata. Its causes are:
  - *Physiological:* It may be normally extensor in infants below 6 months, during deep sleep, under general anesthesia.
  - *Pathological:* Lesion of corticospinal (pyramidal) tract above S1 segment, deep coma, transiently after seizure, alcohol intoxication, hypoglycemia and metabolic encephalopathy.

Alternative ways to elicit Babinski's sign

Chaddock's (lateral malleolus), Gordon's (calf), Oppenheim's (anterior tibia), Schaeffer's (Achilles tendon), Gonda's (press down 4th toe), Stransky's (adduct little toe), Bing's (pinprick on dorsolateral foot).

Deep Tendon Reflex

See **Table 16.3**.

TABLE 16.3: Commonly elicited superficial reflexes and deep tendon reflexes.

Superficial reflexes	*Deep tendon reflexes*
➢ Corneal (cranial nerve V and VII) ➢ Abdominal – Epigastric (T6–T9) – Mid abdominal (T9–T11) – Hypogastric (T11–L1) ➢ Cremasteric (L1, L2) ➢ Anal reflex (S2, S3) ➢ Plantar reflex – Reflexogenic zone—S1 – Afferent nerve—tibial nerve	➢ Jaw jerk (afferent and efferent both 5th nerve, center mid pons) ➢ Biceps (C5, C6) ➢ Brachioradialis/supinator/radial periosteal (C5, C6) ➢ Triceps (C6–C8) ➢ Knee jerk/quadriceps/patellar reflex (L2–L4) ➢ Ankle jerk (L5, S1, S2)
	Latent reflexes (suggest pyramidal lesion if present unilaterally) ➢ Tromner's/finger flexor reflex/ Hoffman's sign ➢ Wartenberg's sign

Vertigo

Q. Write a short note on causes of vertigo.

- **Definition:** Vertigo is defined as an abnormal perception (hallucination/illusion) of movement (a sensation of rotation or tipping) of either the environment or self (body or part of it). The individual feels that the surroundings are spinning or moving. BPPV is the most common cause.

- The perceived movement may be falling down, or rotating or there is a sensation of spinning of the outside world. It is often accompanied by nausea or vomiting.
- **Mechanism:** It develops because of conflicting visual, proprioceptive and vestibular information about a person's position in space. Lesions causing vertigo are listed in **Table 16.4**.

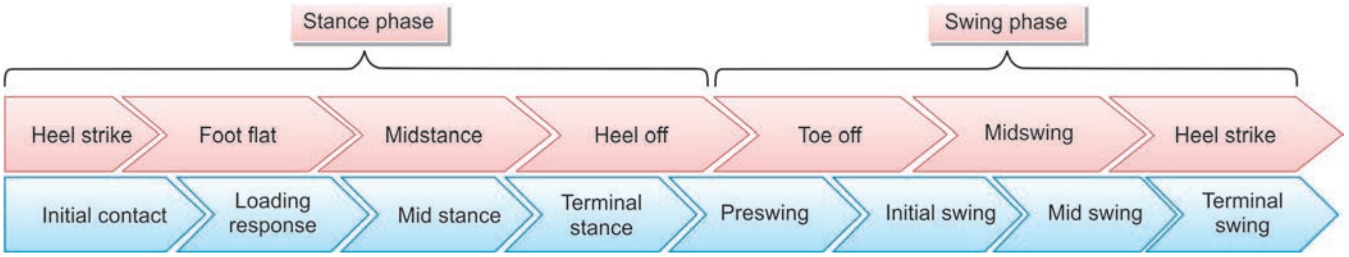
TABLE 16.4: Lesions causing vertigo—the most common cause is benign paroxysmal positional vertigo (BPPV).

Site of lesion	*Example*
Labyrinth	Ménière's disease
VIIIth cranial nerve	Acoustic neuroma
Vestibular neurons	Vertebral artery ischemia, vestibulitis, drugs
Cerebellum/brainstem	Tumor, infarct, multiple sclerosis, drugs, toxins
Temporal lobe	Epilepsy, tumor
Others	Migraine, epilepsy, neurodegenerative diseases

Gait

Observation to be noted while the patient walks: (1) Posture of the body while walking, (2) the regularity of the movement, (3) the position and movement of the arms, (4) the relative ease and smoothness of the movement of the legs, (5) the distance between the feet both in forward and lateral directions, (6) the ability to maintain a straight course, (7) the ease of turning, (8) stopping, and (9) position of feet and posture just before initiation of gait.

Gait Cycle (Fig. 16.2)



Stance phase

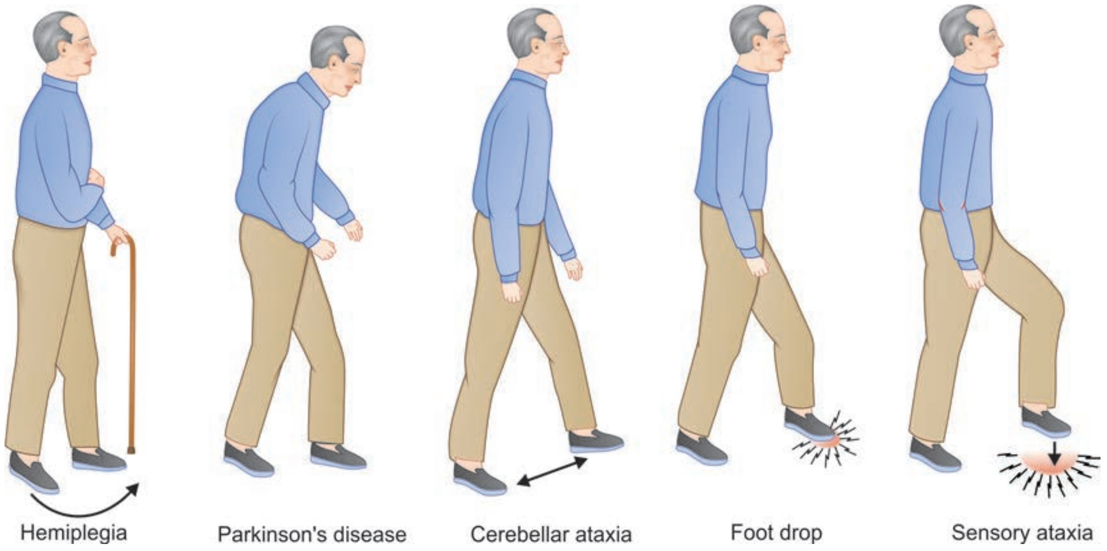
Mid swing
Terminal swing

FIG. 16.2: Phases of the gait cycle.

Abnormalities of Gait (Fig. 16.3)

Q. Write a short note on gait abnormalities with examples.

Neurogenic gait disorders should be differentiated from those due to skeletal abnormalities (characterized by pain producing an antalgic gait, or limp). Gait abnormalities incompatible with any anatomical or physiological deficit may be due to functional disorders.



Hemiplegia
Parkinson's disease
Cerebellar ataxia
Foot drop
Sensory ataxia

FIG. 16.3: Abnormal gait.

Pyramidal (circumduction/hemiplegic) gait

- Lesions of the upper motor neuron produce characteristic extension of the affected leg. There is tendency for the toes to strike the ground on walking and outward throwing/swing of lower limbs. This movement occurring at the hip joint is called circumduction. There is leaning toward the opposite normal side. The arm of the affected side is adducted at the shoulder and flexed at the elbow, wrist, and fingers.
- In hemiplegia/hemiparesis, there is a clear asymmetry between affected and normal sides on walking, but in paraparesis both lower legs swing slowly from the hips in extension and are stiffly dragged over the ground (walking in mud).

Foot drop (high stepping/slapping gait)

In normal walking, the heel is the first part of the foot to hit the ground. A lower motor neuron lesion affecting the leg will cause weakness of ankle dorsiflexion, resulting in a less controlled descent of the foot, which makes slapping noise as it hits the ground. In severe cases, the foot will have to be lifted higher at the knee to allow room for the inadequately dorsiflexed foot to swing through, resulting in a high-stepping gait. Cause: for example, common peroneal nerve palsy.

Myopathic gait/waddling gait (primary muscle disease)

- During walking, alternating transfer of the body's weight through each leg, needs adequate hip abduction.
- **Causes:** Weakness of proximal lower limb muscles (e.g., polymyositis, muscular dystrophy) causes difficulty rising from sitting. The hips are not properly fixed by these muscles and trunk movements are exaggerated, and walking becomes a *waddle or rolling*. The pelvis is poorly supported by each leg. This may be seen with bilateral congenital dislocation of hip (Trendelenburg gait). The patient walks on a broad base with exaggerated lumbar lordosis.

Ataxic gait (cerebellar ataxia: broad-based gait)

- In this type of gait, the patient, unstable, tremulous and reels in any direction (including backward) and walks on a broad base. Ataxia describes this incoordination. The patient finds difficulty in executing tandem walking.
- **Causes:** Lesions of the cerebellum, vestibular apparatus or peripheral nerves. When walking, the patient tends to veer to the side of the affected cerebellar lobe. When the disease involves cerebellar vermis, the trunk becomes unsteady without limb ataxia, with a tendency to fall backward or sideways and is termed truncal ataxia.

Apraxic gait

- In an apraxic gait, the acquired walking skills become disorganized. On examination of the legs, the power, cerebellar function, and proprioception are normal. Leg movement is normal when sitting or lying and the patient can carry out complex motor tasks (e.g., bicycling motion). But patient cannot initiation and organization the motor act of walking. The feet appear stuck to the floor and the patient cannot walk.
- **Causes:** Diffuse bilateral hemisphere disease or diffuse frontal lobe disease (e.g., tumor, hydrocephalus, and infarction).

Marche à petits pas

- It is characterized by small, slow steps and marked instability. In contrast to the festination found in Parkinson's disease, it lacks increasing pace and freezing.
- **Cause:** Small vessel cerebrovascular disease, and accompanying bilateral upper motor neuron signs.

Extrapyramidal gait (shuffling gait)/Festinant gait

- It is characterized by stooped posture and gait difficulties with problems initiating walking and controlling the pace of the gait. Patients make a series of small, flat footed shuffles and become stuck while trying to start walking or when walking through doorways (freezing). The center of gravity will be moved forward to aid propulsion and difficulty stopping. It is characterized by muscular rigidity throughout extensors and flexors. Power is preserved, pace is shortened and slows to a shuffle, and its base remains narrow. There is a stoop and diminished arm swinging and gait becomes festinant (hurried) with short rapid steps. Patient will be having difficulty in turning quickly and initiating movement. Retropulsion (i.e., small backward steps are taken involuntarily when a patient halts).
- **Cause:** Parkinsonism.

Scissoring gait

It may be seen classically with cerebral palsy due to bilateral spasticity.

Sensory ataxia gait (stamping gait)

- It is characterized by broad based, high stepping, stamping gait and ataxia due to loss of proprioception (position sense). This type of ataxia becomes more prominent by removal of sensory input (e.g., walks with eyes closed) and becomes worse in the dark. Romberg's test is positive.
- **Causes:** Peripheral sensory (large fiber) lesions (e.g., polyneuropathy), posterior column lesion (vitamin B_{12} deficiency or tabes dorsalis).

Choreiform gait (hyperkinetic gait)

- The patient will display irregular, jerky, involuntary movements in all extremities. Walking may accentuate their baseline movement disorder.
- **Causes:** Sydenham's chorea, Huntington's disease, and other forms of chorea, athetosis or dystonia.

ABNORMAL SPEECH AND LANGUAGE

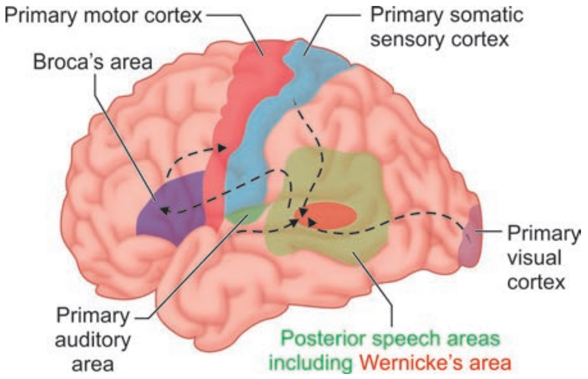
Definitions:

- **Phonation:** It is the production of vocal sounds without word formation.
- **Speech:** It consists of words which are articulate vocal sounds that symbolize and communicate ideas. Speech is the articulation and phonation of language sounds.
- **Language:** It refers to the selection and serial ordering of words according to learned rules by which a person can use spoken or written modalities to communicate with others and to express cerebral activities involved with thinking and learning. It can be by speech (auditory symbols), writing (graphic symbols), or by gestures and pantomime (motor symbols).

Aphasias

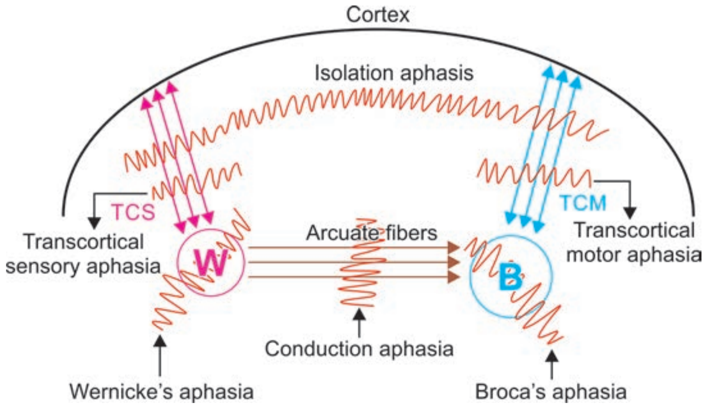
Q. IM18.7 Describe the clinical features and distinguish, based on clinical examination, the various disorders of speech.

- Aphasia is loss or defective language content of speech resulting from damage to the speech centers within the dominant (usually left in 97%) hemisphere. A language disturbance occurring after a right hemisphere lesion in a right hander is known as crossed aphasia **(Figs. 16.4 and 16.5)**.
- It includes defect in or loss of the power of expression by speech, writing or gestures or a defect in or loss of the ability to comprehend spoken or written language or to interpret gestures.
- Aphasia may be categorized according to whether the speech output is fluent or nonfluent.



Primary motor cortex
Primary somatic sensory cortex
Broca's area
Primary visual cortex
Primary auditory area
Posterior speech areas including Wernicke's area

FIG. 16.4: Language and the brain.



Cortex
Isolation aphasia
TCS
Transcortical sensory aphasia
W
Arcuate fibers
B
TCM
Transcortical motor aphasia
Conduction aphasia
Wernicke's aphasia
Broca's aphasia

FIG. 16.5: Schematic representation of aphasias and associated lesions.

  - **Fluent aphasias** (receptive aphasias) are impairments mostly due to the input or reception of language, with difficulties either in auditory verbal comprehension or in the repetition of words, phrases or sentences spoken by others (e.g., Wernicke's aphasia).
  - **Nonfluent aphasias** (expressive aphasias) are difficulties in articulating, with relatively good auditory, verbal comprehension (e.g., Broca's aphasia).

Categories/Varieties of Aphasia (Table 16.5)

- **Alexia:** It is the impairment of visual word recognition, in the context of intact auditory word recognition and writing ability.
- **Agraphia:** It is the inability to write, as a language disorder resulting from brain damage.
- **Anomia:** In this, word approximates the correct answer but it phonetically inaccurate (plentil for pencil)—phonemic paraphasia. When the patient cannot say the appropriate name when an object is shown but can point the object when the name is provided is known as one way or retrieval based naming deficit.

TABLE 16.5: Types of aphasia.

Type of aphasia	*Site of lesion*	*Comprehension*	*Fluency*	*Repetition*	*Reading*	*Writing*	*Naming*
Wernicke's/sensory/ receptive/posterior	Infarction of inferior division of middle cerebral artery	Absent	Preserved	Absent	—	—	—

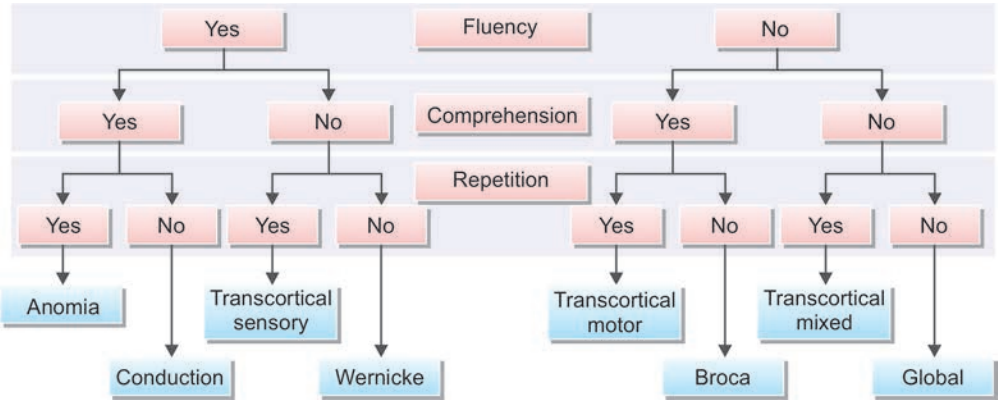
The classification of aphasia has been shown in **Flowchart 16.2**.

FLOWCHART 16.2: Classification of aphasia.



Dysarthria

Dysarthria involve the abnormal articulation of sounds or phonemes.

Types

Types of dysarthria are listed in **Table 16.6**.

TABLE 16.6: Types of dysarthria.

Type	*Description*	*Cause*
Flaccid (lingual, buccal, guttural)	Lower motor neuron (LMN) weakness of facial, lingual or pharyngeal muscles ➢ **Facial paralysis** causes difficulty with labials such as b p m w ➢ **Tongue paralysis** affects a large number sounds, particularly l, d, n, s, t, x ➢ **Palatal paralysis** produces a nasal twang in speech	Cerebrovascular accidents (especially brainstem lesions)
Spastic (hot potato voice)	Strained, slurred hot potato-like voice	Upper motor neuron (UMN) weakness (bilateral), (e.g., pseudobulbar palsy)
Ataxic speech	***Scanning speech***—undue separation of syllables (monosyllable speech) ***Staccato speech***—explosive type of speech with emphasis on syllables	Cerebellar diseases
Hypokinetic	Slow monotonous low voice with inappropriate silence	Extrapyramidal (parkinsonism)
Hyperkinetic dysarthria	Distorted speech with continuous change in articulation	Chorea, athetosis, dyskinesias
Myasthenic dysarthria	Voice is normal in the beginning but becomes weak as sentences progress	Myasthenia gravis

Apraxia

Q. Define apraxia. Give examples.

Apraxia is impaired ability (inability) to carry out (perform) skilled, complex, organized motor activities in the presence of normal basic motor, sensory, and cerebellar function (e.g., complex motor activities—dressing, using cutlery and geographical orientation).

Types

Types of apraxia are listed in **Table 16.7.**

- **Gerstmann's syndrome:** The combination of acalculia (impairment of simple arithmetic), dysgraphia (impaired writing), finger anomia (an inability to name individual fingers such as the index or thumb), and right-left confusion (an inability to tell whether a hand, foot, or arm of the patient or examiner is one the right or left side of the body) is known as Gerstmann's syndrome.

- **Site of lesion:** Inferior parietal lobule (especially the angular gyrus) in the left (dominant) hemisphere.

Agnosia

Q. Write a short note on agnosia.

Agnosia is failure to recognize objects (e.g., places, clothing, persons, sounds, shapes or smells), despite the presence of intact sensory system.

Site of lesion: Contralateral parietal lobe.

Types of agnosia are listed in **Table 16.8.**

Functions of Cerebral Hemispheres

Q. Write a short note on normal functions of different cortical lobes and their abnormalities.

Q. Write a short note on functions of parietal lobe.

Cerebral dominance aligns limb dominance with language function. Right-handed individuals almost always (>95%) have the dominant left hemisphere, and about 7% of left handers have a dominant right hemisphere.

Functions and effects of damage to various lobes of cerebral hemispheres are listed in **Table 16.9** and **Figure 16.6**.

TABLE 16.7: Types of apraxia.

Type	*Description*
Ideomotor apraxia	Most common. It is the inability to perform a specific motor command/act (e.g., cough, lighting a cigarette with a matchstick) in the absence of motor weakness, incoordination, sensory loss or aphasia. Site of lesion is bilateral parietal lobe. Buccofacial apraxia involves apraxic deficits in movements of the face and mouth. Limb apraxia encompasses apraxic deficits in movements of the arms and legs
Dressing apraxia	Site of lesion is nondominant parietal lobe. It is inability to wear his/her dress
Constructional apraxia	It is inability to copy simple diagrams or build simple blocks. Site of lesion is nondominant parietal lobe
Ideational apraxia	It is a deficit in the execution of a goal-directed sequence of movements even with real object (e.g., asked to pick up a pen and write, the sequence of uncapping the pen, placing the cap at the opposite end). This is commonly associated with confusion and dementia rather than focal lesions associated with aphasic conditions
Gait apraxia (Bruns ataxia)	Seen in normal pressure hydrocephalus (NPH)
Gaze apraxia	Part of Balint's syndrome
Other apraxia	Speech apraxia, conceptual apraxia, and conduction apraxia

TABLE 16.8: Types of agnosia.

Type	*Description*
Visual agnosia	Failure to recognize what is seen with eyes despite the presence of intact visual pathways. The individual can describe the shape, color, and size without naming it. Site of lesion is in the posterior occipital or temporal lobes
Prosopagnosia	A type of visual agnosia in which patient cannot identify familiar faces, sometimes the reflection of his or her own face in the mirror even including their own. Site of lesion is parieto-occipital lobe
Simultanagnosia	It is inability to perceive more than one object at a time
Autotopagnosia	It is a form of agnosia, characterized by an inability to localize and orient different parts of the body
Pseudopolymelia	The feeling of false—the feeling of false extremities. More frequent the patients feel the extremities. More frequent the patients feel the third-hand
Anosognosia	It is an inability or refusal to recognize a defect or disorder that is clinically evident
Auditory agnosia	Heartfelt deafness: It consists in the loss of ability to know objects on sounds characteristic for them (clock—on ticking)

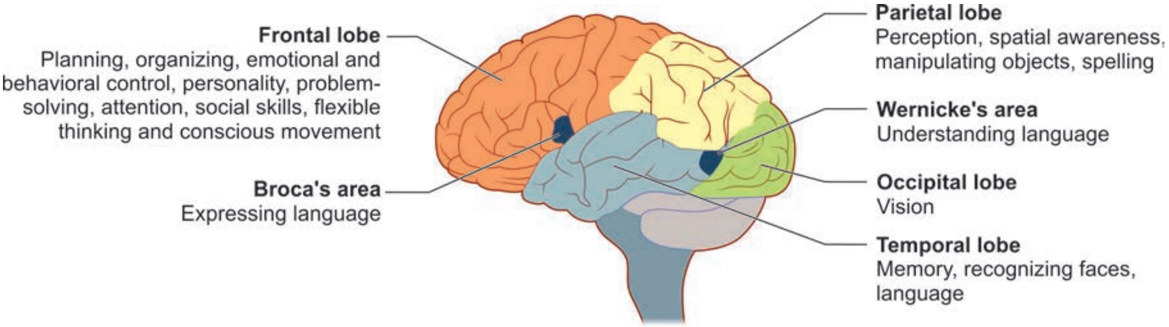
TABLE 16.9: Functions and effects of damage to various lobes of cerebral hemispheres.

Lobe	*Function*	*Cognitive/behavioral effects of damage*
Frontal Please **SMILE** (Mnemonic)	**P**ersonality	Disinhibition
	Social behavior	Lack of initiation
	Micturition	Antisocial behavior
	Intelligence	Impaired memory
	Language	Expressive dysphasia
	Emotional response	Incontinence
Parietal: Dominant side	Language	Dysphasia, dyslexia
	Calculation	Acalculia
	Others	Apraxia, agnosia
Parietal: Nondominant side	Spatial orientation	Spatial disorientation, neglect of contralateral side
	Constructional skills	Constructional apraxia, dressing apraxia

Contd...

Contd...

Lobe	*Function*	*Cognitive/behavioral effects of damage*
Temporal: Dominant side	Auditory perception	Receptive aphasia
	Language	Dyslexia
	Verbal memory	Impaired verbal memory
	Smell	
	Balance	
Temporal: Nondominant side	Auditory perception	Impaired nonverbal memory
	Melody/pitch perception	Impaired musical skills (tonal perception)
	Nonverbal memory	
	Smell	
	Balance	
Occipital	Visual processing	Visual inattention, visual loss, visual agnosia (Anton–Babinski syndrome)



Frontal lobe
Planning, organizing, emotional and behavioral control, personality, problem-solving, attention, social skills, flexible thinking and conscious movement
Broca's area
Expressing language
Parietal lobe

HEADACHE

Q. IM17.1 Define and classify headache and describe the presenting features, precipitating factors, aggravating and relieving factors of various kinds of headache.

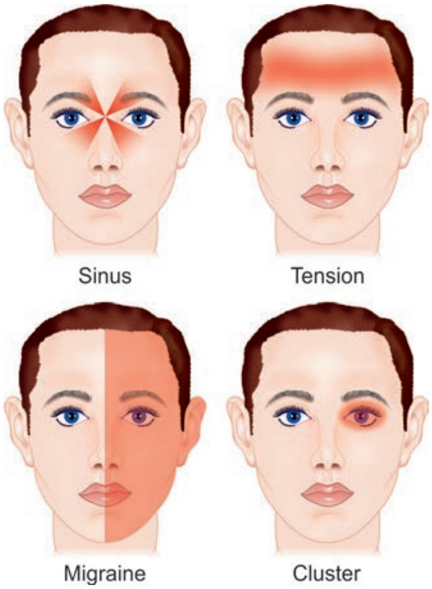
Headache is among the most common reasons, patients seek medical attention.

Classification of Headache (Table 16.10 and Fig. 16.7)

- **Primary headaches:** Benign, recurrent, no organic disease as their cause. It affects the quality of life of the patient.
- **Secondary headaches:** Underlying organic disease.

TABLE 16.10: Classification of headache.

Primary headache		*Secondary headache*
Type	*Percent (%)*	➢ Head or neck trauma ➢ Cranial or cervical vascular disorder—arterial dissection, cerebral venous thrombosis ➢ Noninfectious inflammatory disease – Intracranial neoplasm – High and low cerebrospinal fluid pressure headache ➢ Substance use or its withdrawal ➢ Disorder of homeostasis—hypoxia, hypercarbia, hypoglycemia ➢ Psychiatric disorder—somatization ➢ Cranial neuralgia ➢ Infection—meningitis ➢ Disorder of cranium, neck, face, eyes, ears, nose, sinus, teeth, mouth, or other facial structure
Tension-type	69	
Migraine	16	
Idiopathic stabbing	2	
Exertional	1	
Cluster	0.1	
Other primary headache ➢ Paroxysmal hemicrania ➢ SUNCT = Short-lasting unilateral neuralgiform headache attacks with conjunctival injection and tearing ➢ SUNA = Short-lasting unilateral neuralgiform headache attacks with cranial autonomic symptoms		



Sinus
Tension
Migraine
Cluster

FIG. 16.7: Headache types.

MIGRAINE

Q. IM17.3 Classify migraine and describe the distinguishing features between classical and nonclassical forms of migraine.

Migraine is a neurovascular disease caused by neurogenic inflammation and characterized by severe, recurring headaches.

- It is the second most common cause of headache. It is usually characterized by an episodic severe pain on one side of the head (headache) and usually associated with certain features such as sensitivity to light, sound or movement; nausea and vomiting often accompany the headache.
- Gender—Female: Male ratio is 5:1.

Classification

Q. Classify migraine and describe the distinguishing features between classical and nonclassical forms of migraine.

- **Migraine without aura or common migraine:** It does not give any warning signs before the onset of headache. It occurs in about 70–80% of migraine patients.
- **Migraine with aura or classical migraine:** It gives some warning signs called "aura" before the actual headache begins. About 20–30% migraine patients experience aura. The most common aura is visual and may include both positive and negative (visual field defects) features.
- **Retinal migraine:** It involves attacks of monocular scotoma or even blindness of one eye for less than an hour and associated with headache.
- **Childhood periodic syndromes:** It involves cyclical vomiting (occasional intense periods of vomiting), abdominal migraine (abdominal pain, usually accompanied by nausea), and benign paroxysmal vertigo of childhood (occasional attacks of vertigo). They may be precursors or associated with migraine.
- **Complicated migraine:** It describes migraine headaches and/or auras that are unusually long or unusually frequent, or associated with a seizure or brain lesion.
- **Basilar migraine:** Occipital headache, preceded by vertigo, diplopia and dysarthria, ±visual and sensory symptoms (brainstem symptoms).
- **Hemiplegic migraine:** Rare autosomal dominant disorder characterized by prolonged headache lasting hours or days, followed by hemiparesis and/or coma that recovers slowly over days.
- **Ophthalmoplegic migraine:** Migraine associated with transient IIIrd nerve palsy with/without involvement of pupil; sometimes also affect IVth and VIth nerve.
- **Vestibular migraine** (also called migrainous vertigo or migraine-associated vertigo).
- **Catamenial migraine:** Migraine associated with menstruation-associated migraine.

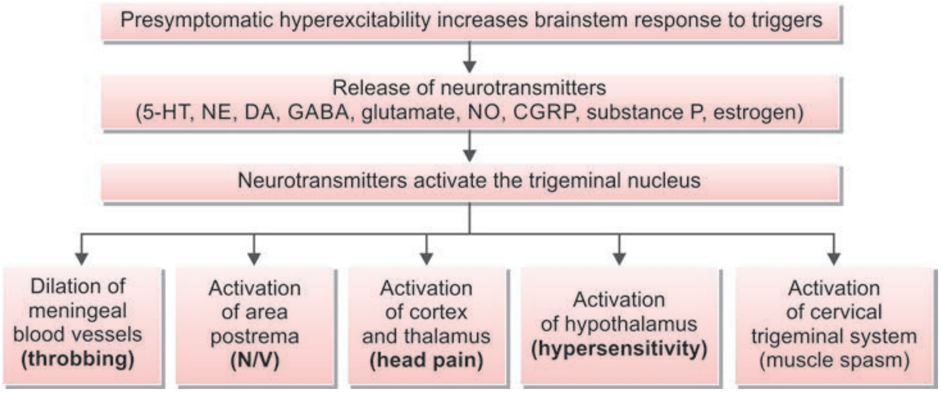
Pathogenesis

- Cause of migraine is not known.
- **Genetic factors:** Play a role in causing the neuronal hyperexcitability. Migraine is usually polygenic. Rarely, familial migraine is associated with mutations in the α1 subunit of the P/Q-type voltage-gated calcium channel or neuronal sodium channel (SCN1A), and **a dominant** loss of function mutation in a potassium channel gene (TRESK). Migraine is frequently associated with positive family history, and similar phenomena occur in disorders such as CADASIL.
- Genes for **familial hemiplegic migraine:**
  - FHM1—CACNA1A: Neuronal P/Q calcium channel—increases neurotransmitter release
  - FHM2—ATP1A2: Astrocyte sodium pump—dysfunction increases extracellular K^+
  - FHM3—SCN1A: Neuronal sodium channel—increased action potential firing
- **Hormonal influences:** Female preponderance and the frequency of migraine attacks at certain points in the menstrual cycle due to hormonal fluctuations. Estrogen-containing oral contraception can exacerbate migraine in few patients.
- **Right-to-left cardiac shunt:** Migraine with aura has been associated with patent foramen ovale (PFO), atrial septal defect (ASD), and pulmonary arteriovenous malformations (AVMs) in hereditary hemorrhagic telangiectasia (Osler–Weber–Rendu syndrome).

Several theories have been proposed for the pathogenesis of migraine **(Flowchart 16.3)**.

- **Vascular theory:** Constriction of intracerebral blood vessel produces aura. Vasodilatation of intracranial/extracranial blood vessel produces headache phase.

FLOWCHART 16.3: Pathogenesis of migraine.



Presymptomatic hyperexcitability increases brainstem response to triggers
Release of neurotransmitters (5-HT, NE, DA, GABA, glutamate, NO, CGRP, substance P, estrogen)
Neurotransmitters activate the trigeminal nucleus
Dilation of meningeal blood vessels (throbbing)
Activation of area postrema (N/V)
Activation of cortex and thalamus (head pain)
Activation of hypothalamus (hypersensitivity)
Activation of cervical trigeminal system (muscle spasm)

(5-HT: 5-hydroxytryptamine; NE: Norepinephrine; DA: Dopamine; GABA: Gamma-aminobutyric acid; NO: Nitric oxide; CGRP: Calcitonin gene-related peptide)

- **Serotonin theory:** Decreased serotonin levels linked with migraine and specific serotonin receptors found in blood vessels of brain.
- **Neurogenic theory:** The aura (*see clinical features below*) is thought to be due to spreading cortical depression wave of neuronal depolarization followed by depressed activity spreading slowly anteriorly across the cerebral cortex from the occipital region. This spreading process occurs at a rate of about 3 mm/minute. Dysfunction of activation of cells in the trigeminal nucleus releases vasoactive neuropeptides [e.g., calcitonin gene-related peptide (CGRP), substance P, and other vasoactive peptides including 5-HT] by activated trigeminovascular neurons. They produce painful meningeal inflammation and vasodilation.
- Dopamine plays a role and most migraine symptoms can be induced by dopaminergic stimulation. There is dopamine receptor hypersensitivity in patients with migraine.

Cortical Spreading Depression

- Wave of activation followed by reduced activity that spreads across the surface of the brain.
- Initial dilation conducted with intrinsic velocity ahead of cortical spreading depression (CSD), subsequent constriction, and eventual dilation.

Astrocyte Calcium Waves

- Slowly propagated waves evoked by wide variety of stimuli
- Associated with active release of: ATP, glutamate, K^+, lactate, prostanoids, and interleukins (ILs)

Precipitating factors: Anything can initiate or precipitate or amplify an attack. Common triggers are: excess stress, glare, exposure to bright light, loud noises/sounds, smoke or strong scents, menstruation, lack or excess of sleep, cheese, caffeine, alcohol, chocolate, citrus fruit, food additives such as monosodium glutamate, vasodilators, hunger, physical exertion, stormy weather or barometric pressure changes, contraceptive pills, etc.

Clinical Features

Headache is usually hemicranial, throbbing, and associated with nausea and vomiting.

- **Migraine without aura** (previously called "common" migraine).
    - About 70–80% of patients with migraine have characteristic headache but without aura.
    - Typically attacks are episodic and start at puberty and prevalence increases in 4th decade. It may show variable degree of spontaneous remissions.
    - The scalp may be tender to touch during episodes (allodynia is production of pain from normally nonpainful stimuli) and the patients prefer to be still in a dark and quiet environment.
    - Other symptoms associated with migraine headache are listed in **Table 16.11.**
- **Migraine with aura** (previously known as "classical" migraine)
    - *Migraine aura:* About 20–30% of patients with migraine experience malaise, irritability, behavioral change or focal neurological symptoms for some hours or days immediately preceding the headache phase.

TABLE 16.11: Symptoms associated with migraine headache.

Nausea	Vomiting
Photophobia, prostration	Visual disturbances
Lightheadedness	Paresthesias
Scalp tenderness/cutaneous allodynia	Vertigo

Type of aura: (1) visual aura, (2) sensory aura, or (3) language aura.

- *Visual aura:* It is the most common type characterized by positive visual symptoms such as shimmering, teichopsia (silvery zigzag lines also called **fortification spectra**) flashing lights or fragmentation of the image (like looking through a pane of broken glass) or scintillating spots across the visual fields for up to 40 minutes. Sometimes there may be temporary patchy visual field loss which may move across the visual field (scotomas) and even evolve into hemianopia or tunnel vision.
- *Sensory aura:* It consists of positive sensory symptoms such as tingling followed by numbness, spreading over 20–30 minutes, from one part of the body to another.
- *Language aura:* Dominant hemisphere involvement may cause transient speech disturbance.
- Motor aura-transient weakness.

Duration of aura: Usually it evolves over 5–20 minutes with symptoms changing as the wave of spreading neuronal depression moves across the surface of the cortex. It rarely lasts for >60 minutes and is followed immediately by the headache phase **(Fig. 16.8)**.

FIG. 16.8: Migraine phases.

Diagnostic Criteria (Table 16.12)

Strongest predictors of migraine

- Are you nauseated or sick to your stomach when you have a headache?
- Has a headache limited your activities for a day or more in the last 3 months?
- Does light bother you when you have a headache?
- Patients who answer positively to two out of three have a 93% chance of having migraines.

TABLE 16.12: Simplified diagnostic criteria for migraine.

Repeated attacks of headache lasting 4–72 hours (untreated) with	
At least two of the following features:	Plus at least one of the following features:
➢ Unilateral pain	➢ Nausea/vomiting
➢ Throbbing pain	➢ Photophobia and phonophobia
➢ Motion sensitivity (headache aggravated with head movement or physical activity)	➢ Normal physical examination, no other reasonable cause for the headache
➢ Moderate or severe intensity	

Complications of Migraine

- **Status migrainosus** is a debilitating migraine attack lasting for >72 hours.
- Persistent aura without infarction is defined by aura symptoms persisting for 1 week or more with no evidence of infarction on neuroimaging.
- **Migrainosus infarction:** Migraine attack, occurring in a patient with migraine with aura, in which one or more aura symptoms persist for >1 hour and neuroimaging shows an infarction in a relevant brain area.
- Migraine aura-triggered seizure is a seizure triggered by an attack of migraine with aura.

Red Flags of Headache

They have been shown in **Box 16.4**.

Box 16.4: Red flags of headache.

- "Worst" headache ever
- First severe headache
- Subacute worsening over days or weeks
- Altered level of sensorium/consciousness
- Abnormal neurologic examination
- Fever or unexplained systemic signs
- Significant weight loss
- Vomiting that precedes headache
- Pain induced by bending, lifting, cough, worsens with Valsalva maneuvers
- Pain which disturbs sleep or presents
- immediately upon awakening
- Known systemic illness, history of trauma, cancer or HIV
- New-onset headache in a patient
- >50 years of age
- Focal neurologic deficits, jaw claudication
- Morning headache associated with nausea and vomiting
- Pain associated with local tenderness (e.g., region of temporal artery)

Mnemonic SNNOOP10

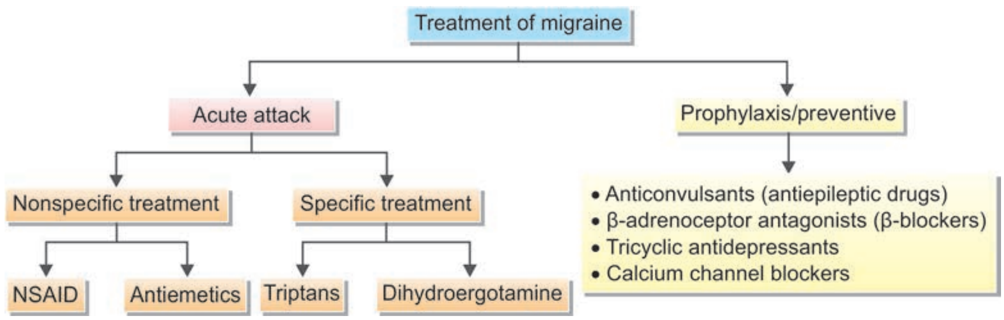
- **S**ystemic symptoms including fever
- **N**eoplasm history
- **N**eurologic deficit (including decreased consciousness)
- **O**nset is sudden or abrupt
- **O**lder age (onset after age 50 years)
- **P10:**
  1. **P**attern change or recent onset of new headache
  2. **P**ositional headache
  3. **P**recipitated by sneezing, coughing, or exercise
  4. **P**apilledema
  5. **P**rogressive headache and atypical presentations
  6. **P**regnancy **or p**uerperium
  7. **P**ainful eye with autonomic features
  8. **P**ost-traumatic onset of headache
  9. **P**athology of the immune system such as HIV
  10. **P**ainkiller (analgesic) overuse (e.g., medication overuse headache) or new drug at onset of headache

Q. IM17.11 **Describe the indications, pharmacology, dose, side effects of abortive therapy in migraine.**

Q. **Write a short essay/note on management of migraine in young adults. Mention three drugs used and write short note on prophylactic therapy.**

Q. IM17.12 **Describe the indications, pharmacology, dose, side effects of prophylactic therapy in migraine.**

FLOWCHART 16.4: Treatment of migraine.



Management (Flowchart 16.4)

Nonpharmacological treatment (general measures)

- Explanation that migraine has no grave prognosis.
- Identification of triggers and avoidance of identified triggers or exacerbating factors to prevent attacks. Women with aura should avoid estrogen treatment (oral contraception or hormone replacement). Lifestyle modification wherever possible.
- Other measures: Meditation, relax techniques, psychotherapy.

Pharmacological treatment

- **Abortive treatment:** Treatment of acute attack.
- **Preventive treatment:** Drug prophylaxis.

Treatment of an acute attack

- **Analgesic:** Simple analgesia such as aspirin, paracetamol or nonsteroidal anti-inflammatory agents.
- Nausea may be treated by an antiemetic (metoclopramide or domperidone).
- **Severe attacks:** If there is previously no relief with a nonsteroidal anti-inflammatory drug (NSAID), use "triptans".

- *Triptans* (e.g., *sumatriptan*: 50–100 mg tablet/5–20 mg nasal spray/6 mg S/C; *rizatriptan*: 5–10 mg tablet; *frovatriptan*: 2.5 mg oral; naratriptan: 2.5 mg oral; *almotriptan*: 12.5 mg oral; *eletriptan*: 40–80 mg oral; *zolmitriptan*: 2.5 mg oral/5 mg intranasal spray):
    - *Mode of action:* Potent 5-HT1B/1D agonists, inhibit release of CGRP and substance P, inhibit activation of the trigeminal nerve, and inhibit vasodilation in the meninges.
    - *Administration:* Triptans are available as oral preparations, nasal spray, and subcutaneous injections.
    - *Contraindications:* Ischemic heart disease or stroke, high risk for coronary artery disease, pregnancy, hemiplegic or basilar migraine and use with ergots.
- Calcitonin gene-related peptide antagonists (e.g., **erenumab, fremanezumab, galcanezumab**) are very effective for acute treatment of migraine.
- **Lasmiditan**, a selective serotonin 1F receptor agonist has been tried.
- Single-pulse **transcranial magnetic stimulation** (TMS) has shown good benefits.

Drug prophylaxis

- Indications for drug prophylaxis in migraine are listed in **Box 16.5**. Various drugs can be used and the most frequently used are:
    - Anticonvulsants [antiepileptic drugs (AEDs)]: **Valproate** (800 mg) or **topiramate** (100–200 mg daily) is the most effective option.
    - β-adrenoceptor antagonists (β-blockers) (e.g., **propranolol** slow-release 40–120 mg daily).
    - Tricyclic antidepressants [e.g., **amitriptyline** 10 mg increasing weekly in 10 mg steps to 50–60 mg or Dosulepin (25–75 mg at night)].
    - Methysergide 1–2 mg TID in resistant cases (prolonged use may produce retroperitoneal and mediastinal fibrosis).
    - Botulinum toxin has been tried as a treatment for chronic migraine.
    - Vasoactive drugs and calcium channel blockers: These include **flunarizine** (5–10 mg OD at bedtime), verapamil (80–160 mg 3 times a day), and methysergide and are used in refractory cases. Pizotifen is rarely used.
    - **Memantine**—N-methyl-D-aspartate (NMDA) receptor antagonist, blocks glutamate
    - Nonprescription medications:
        - Riboflavin (B_2): 400 mg daily
        - Magnesium oxide: 400 mg daily
        - Coenzyme Q10: 150 mg daily
        - Feverfew: 10–30 mg daily
        - Butterbur (Petadolex): 50–75 mg BID
        - Melatonin

Box 16.5: Indications for drug prophylaxis in migraine.

- Patients who have very frequent headaches (>2–3 weeks)
- Attack duration >48 hours
- Migraine-related disability >3 days/month
- Headache extremely severe
- Migraine accompanied by severe aura
- Contraindication to acute treatment
- Unacceptable adverse effects with acute migraine treatment
- Patients preference

Cluster Headache

Q. Write a short note on cluster headache.

Cluster headache (migrainous neuralgia) is distinct from migraine and is much less common than migraine.
Age and gender: Usually it occurs in young adult in the 3rd decade (20 and 40 years) with male predominance (M:F = 5:1).

Pathophysiology

- Cause and precise mechanism are unknown.
- It differs from migraine in its character, absence of genetic predisposition, lack of triggering dietary factors, male predominance, and different drug effect.
- Abnormal hypothalamic activity is observed on functional imaging studies during an attack. Patients are often smokers and consume more than average alcohol.

Clinical Features

- Cluster headache is **periodic with recurrent bouts** of identical headaches beginning at the **same hour for weeks at a time** (the eponymous "cluster"). Patients may develop either one or several attacks within a 24-hour period.

- Cluster headache causes **severe (excruciating) and worst, stabbing/boring, unilateral periorbital/retro-orbital pain with parasympathetic autonomic features** in the same eye (e.g., unilateral lacrimation, nasal congestion, and conjunctival redness/injection or even a transient Horner's syndrome). The pain is so severe that they may commit suicide.
- **Circadian periodicity:** Usually cluster period lasts for few weeks and followed by remission for months to years. They typically recur a year or more later often at the same time of year.

Diagnostic Criteria for Cluster Headache

Diagnostic criteria for cluster headache have been shown in **Box 16.6**.

Management of Cluster Headache

- **Acute attacks:** Analgesics are not useful and acute attacks are usually halted by:
  - **Subcutaneous injection of sumatriptan** (6 mg) is the drug of choice for acute treatment. It works quickly and usually shortens an attack to 10–15 minutes. There is no evidence of tachyphylaxis. Oral sumatriptan is not effective. Sumatriptan (20 mg) and zolmitriptan (5 mg) nasal sprays are also effective
  - **Inhalation of 100% oxygen** at 10–12 L/minute for 15–20 minutes.
  - Many respond very well.
  - The brevity of the attack probably prevents other migraine therapies from being effective. **Octreotide** is effective in the treatment of acute cluster headaches.
- **Most prophylactic migraine drugs are often ineffective:** Attacks can be prevented in some patients by sodium valproate, lithium, verapamil, methysergide and/or a short course of oral corticosteroids.
- **Neuromodulation therapy:** Used when medical therapies fail in cluster headaches, sphenopalatine ganglion stimulation has been shown to be beneficial.

Box 16.6: Diagnostic criteria for cluster headache.

At least five attacks fulfilling following:
- Severe or very severe unilateral orbital, supraorbital and/or temporal pain lasting 15–180 minutes if untreated
- Headache is accompanied by at least one of the following:
  - Autonomic features: Unilateral
    - Conjunctival redness/injection and/or lacrimation or
    - Nasal congestion and/or rhinorrhea or
    - Edema of eyelid
    - Sweating on the forehead and face or
    - Miosis and/or ptosis or
  - Restlessness or agitation
- Frequency of attacks: From one every other day to eight/day

Tension-type Headache

Q. Write a short note on tension headache.

It is the most common type of headache.

Pathophysiology is incompletely understood, and few consider this as a milder version of migraine.

Clinical Features

Characteristic features of headache **(Fig. 16.9)** are:
- Pain is "dull" "tight" or like a "pressure", and it may be accompanied by a sensation of a band round the head or pressure at the vertex.
- It is of constant character and generalized, but often radiates forward from the occipital region. It may be episodic or persistent.
- Severity may vary, and is not associated vomiting or photophobia. The pain often progresses throughout the day.
- Tenderness may be present over the skull vault or in the occiput.

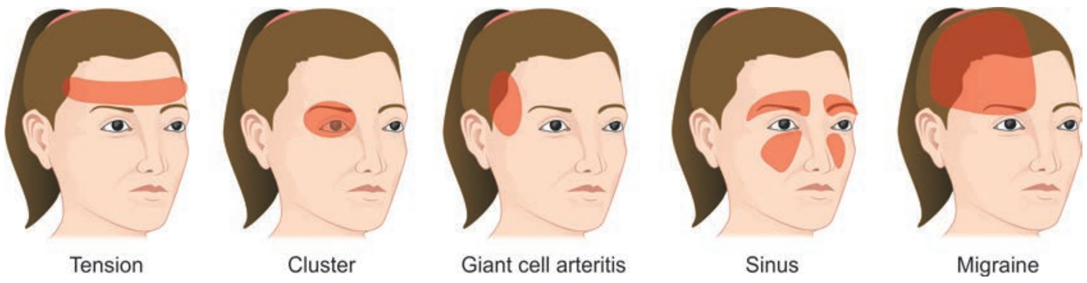


FIG. 16.9: Common primary headaches—characteristic features.

Management

- Simple analgesics like acetaminophen, aspirin or NSAIDs can be used for acute relief.
- Carefully assess, followed by discussion of likely precipitants and reassurance that the prognosis is good.
- Physiotherapy (with muscle relaxation and stress management) may be helpful.
- Low-dose amitriptyline may be beneficial especially in patients with chronic tension headache. Investigation is rarely required.

The differences between most common primary headaches are presented in **Table 16.13**.

TABLE 16.13: Comparison of most common primary headaches.

Characteristic	***Migraine***	***Tension***	***Cluster***
Age of onset	25–55 years	30–50 years	20–40 years
Location	60–70% unilateral	Bilateral	Unilateral, orbital, supraorbital, temporal
Duration of episode	4–72 hours	30 minutes to 7 days	15–180 minutes
Severity	Moderate to severe	Mild to moderate	Extremely severe
Type	Pulsating, throbbing	Pressing, tightening but not pulsating	Boring, searing
Pattern	1–2 attacks per month	<180 attacks per year (or <15 attacks per month)	1–8 attacks per day separated by pain-free periods
Associated symptoms	Nausea, vomiting, photophobia, phonophobia (two of these)	Either photophobia or phonophobia, but not both, no nausea or vomiting	Conjunctival injection, lacrimation forehead/facial swelling, nasal congestion, rhinorrhea, ptosis, miosis, eyelid edema

New Daily Persistent Headache (NDPH)

This disorder is characterized by a daily and unremitting headache that becomes continuous shortly (<3 days) after onset, without a precipitating factor or a prior headache history. It has features of both migraine and tension-type headache.

Hemicrania Continua

- Hemicrania continua is characterized as a continuous, strictly unilateral headache of mild to moderate intensity with superimposed exacerbations of more severe pain.
- During these exacerbations, one or more autonomic symptoms (ptosis, conjunctival injection, lacrimation, and nasal congestion) occur ipsilateral to the pain.
- This headache is defined by its absolute response to therapeutic doses of indomethacin.

Q. IM17.10 **Enumerate the indications for emergency care admission and immediate supportive care in patients with headache.**

Symptoms	***Features and possible etiology***
Systemic symptoms and secondary risk	Fever, loss of appetite, loss of weight and other constitutional symptoms that may suggest a systemic disease such as malignancy or systemic inflammatory condition; immunocompromised state
Neurologic deficit	Suggestive of focal pathology
Older age (after 50 years)	New onset of headache, change in characteristics of headache at older age
Onset of headache	Thunderclap characteristics that can suggest subarachnoid hemorrhage, headaches due intracranial hemorrhage, reversible cerebral vasoconstriction syndrome, cranial or other cervical vascular disorders
Pattern change of headache	Need to re-evaluate for new etiology
Papilledema	Indication of raised intracranial pressure (ICP)
Painful eye with autonomic features	Painful red eyes, increased lacrimation, rhinorrhea, ptosis etc., that can suggest headaches due to ophthalmologic causes (e.g., glaucoma), lesions in pituitary, Tolosa Hunt syndrome, etc.
Painkiller overuse or new drug at onset of headache	Medication overuse headache; side effects of medications
Positional headaches	Headache worse on lying down suggests raised ICP while those worse in upright positions suggest low ICP
Post-traumatic headache	Postconcussion syndrome; intracranial hemorrhage; cervical artery dissection, etc.
Precipitating activity	Headaches precipitated by sneezing, coughing or exercise is suggestive of raised ICP
Pregnancy or puerperium	Headaches due to cerebral venous sinus thrombosis, hypertension related disorders (e.g., preeclampsia/eclampsia), other cranial or cervical vascular disorders, etc.
Behavioral or personality change	Encephalopathy/encephalitis
Associated symptomatology	Fever, neck stiffness, seizures, or abnormal movements
Developmental delay or regression	To consider for underlying malignancy or neurometabolic conditions
Genetic disorders	Can predispose to malignancies and other intracranial pathologies such as neurocutaneous syndromes (Neurofibromatosis Type 1 and 2, Sturge Weber syndrome, tuberous sclerosis)
Early morning vomiting without nausea	Suggests raised ICP

STROKE AND CEREBROVASCULAR DISEASE

Q. IM18.2 Classify cerebrovascular accidents and describe the etiology, predisposing genetic and risk factors pathogenesis of hemorrhagic and nonhemorrhagic stroke.

Q. Describe clinical features, diagnosis of the cerebral stroke in young, and its management.

Q. Describe the etiology, clinical features, and treatment of cerebral thrombosis.

Q. Write a short essay/note on cerebrovascular accidents/stroke.

Stroke

- **A stroke (cerebrovascular accident is a vague** term which should be avoided) is defined as a syndrome of rapid **(abrupt) onset of a neurologic deficit** that is attributable to a focal vascular cause.
- **World Health Organization (WHO) definition:** Stroke is a defined as a clinical syndrome consisting of **"rapidly developing clinical signs of focal (or global) disturbance of cerebral function, with symptoms lasting for 24 hours or longer or leading to death, with no apparent cause other than of vascular origin".**
- **Progressing stroke (or stroke in evolution):** It is a stroke in which the focal neurological deficit worsens after the patient first presents. It may be due to increasing volume of infarction, secondary hemorrhage in the infarcted area or increasing cerebral edema.
- **Complete stroke:** Rapid onset with persistent focal neurological deficit which does not progress beyond 96 hours.
- **Evolving stroke:** Gradual stepwise development of neurological deficits.

Focal cerebral deficits that develop slowly (over weeks to months) are unlikely to be due to stroke and are more suggestive of tumor or inflammatory or degenerative disease.

Terminologies

Several terms are used to classify strokes, mainly based on the duration and evolution of symptoms.

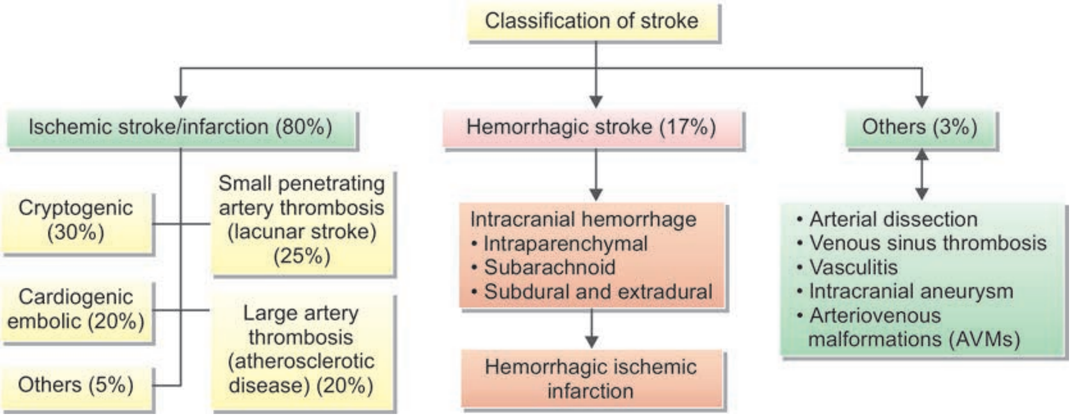
- **Transient ischemic attack (TIA):** Described later
- **Reversible ischemic neurological deficit (RIND):** In some cases, deficits last for longer than 24 hours but resolve completely or almost completely within a few days.
- **Stuttering hemiplegia:** Internal carotid lesions are characterized by repeated episodes of TIA followed by fully evolved stroke.

Types of Stroke (Flowchart 16.5)

About 80% of patients develop **cerebral infarction** due to inadequate blood flow to part of the brain, and most of the remainder develops an **intracerebral hemorrhage.**

- **Ischemic stroke: Cerebral infarction is most commonly caused by thromboembolic disease** secondary to atherosclerosis in the major extracranial arteries (carotid artery and aortic arch). About 20% of infarctions are caused by emboli from the heart, and about 20% are caused by thrombosis in situ caused by intrinsic disease of small perforating vessels (lenticulostriate arteries), producing lacunar infarctions.

FLOWCHART 16.5: Classification of stroke.



Classification of stroke
Ischemic stroke/infarction (80%)
Hemorrhagic stroke (17%)
Others (3%)
Cryptogenic (30%)
Small penetrating artery thrombosis (lacunar stroke) (25%)
Cardiogenic embolic (20%)
Large artery thrombosis (atherosclerotic disease) (20%)
Others (5%)
Intracranial hemorrhage
• Intraparenchymal
• Subarachnoid
• Subdural and extradural
Hemorrhagic ischemic infarction
• Arterial dissection
• Venous sinus thrombosis
• Vasculitis
• Intracranial aneurysm
• Arteriovenous malformations (AVMs)

- **Hemorrhagic stroke:** Intracranial hemorrhage (ICH) is caused by bleeding directly into or around the brain. Neurological symptoms are produced by compression, toxic effects or raised intracranial pressure (ICP).
- **Hemorrhagic conversion of ischemic stroke**
    - This may occur after thrombolytic drugs (alteplase) are administered to patients with an ischemic stroke or where a patient has a large cerebral clot, which tends to be more common with cardioembolic strokes.
    - The major adverse effect of thrombolysis is symptomatic intracerebral hemorrhage, observed in around 6–7% of cases.
    - The risk of symptomatic ICH increases with age, high blood pressure, very severe neurological deficits, severe hyperglycemia, and with early ischemic changes on computed tomography (CT) scans.
- **Cerebrovascular anomalies** such as intracranial aneurysm and AVMs.

Risk (Predisposing) Factors for Stroke (Box 16.7)

Q. Write a short essay/note on risk factors for stroke.

Box 16.7: Risk factors for stroke.

Risk factors in patients of all age groups

High-risk

- Hypertension (including isolated systolic)
- Smoking
- Diabetes mellitus
- Atrial fibrillation
- **Drugs:** Cocaine, amphetamine
- Dilated cardiomyopathy
- Endocarditis
- High cholesterol
- Obesity
- **Vasculitis:** Systemic vasculitis [e.g., polyarteritis nodosa (PAN)], granulomatosis with polyangiitis (Wegener's, etc.), primary CNS vasculitis, meningitis (syphilis, tuberculosis, fungal, bacterial, zoster)

Low-risk

- Migraine
- Oral contraceptives or alcohol
- Patent foramen ovale
- Recent myocardial infarction
- Prosthetic valve
- Sleep apnea

Additional risk factors that are more common in young patients

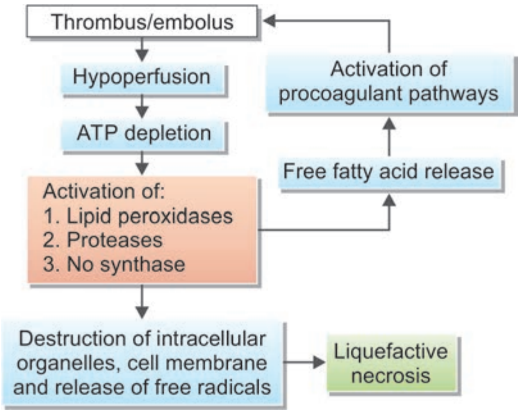
Hypercoagulable disorders

- Protein C and S deficiencies
- Antithrombin III deficiency
- Antiphospholipid syndrome
- Factor V Leiden mutation
- Prothrombin G20210A heterozygous mutation
- Sickle cell anemia
- Hyperhomocysteinemia
- Thrombotic thrombocytopenic purpura
- Arterial dissection
- Infections (e.g., syphilis, HIV)
- Systemic malignancy

Pathophysiology (Flowchart 16.6)

- Complete stop of cerebral blood flow (CBF) causes death of brain tissue within 4–10 minutes. The CBF to the ischemic core is <10 mL/100 g/minute.
- Ischemic penumbra **(Fig. 16.10)** is the region surrounding the central core. The tissue of the penumbra is functionally impaired and is at risk of infarction. CBF is 10–18 mL/100 g/minute. It has the potential to be salvaged by revascularization. The damage of the penumbra is coupled by inflammation and excitotoxicity mediated by glutamine and sodium. Also, hyperglycemia and fever worsen the penumbra, so need to be controlled.

FLOWCHART 16.6: Pathophysiology of ischemic stroke.



(ATP: Adenosine triphosphate)

Etiology of Ischemic Stroke (Box 16.8)

Embolic occlusion

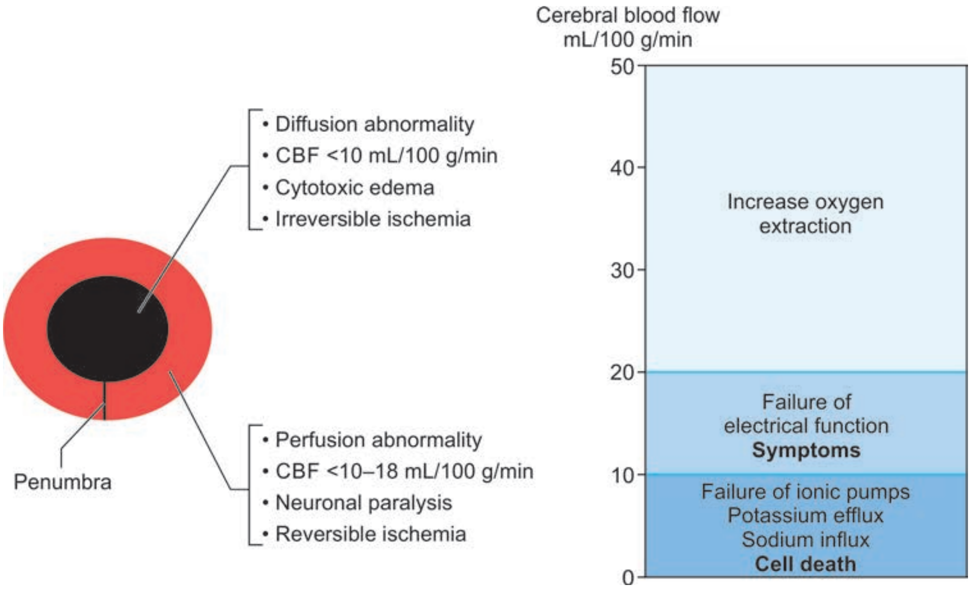
Q. Write a short essay/note on embolic stroke, its causes, and management.

Artery-to-artery embolic stroke

- **Any vessel** may be the source of emboli, including the aortic arch, common and internal carotid, vertebral and basilar arteries.
- **Atherosclerosis within the carotid artery:** Carotid bifurcation atherosclerosis is the most common source of artery-to-artery embolus.
- **In young (age <60 years) patients:** Intracranial atherosclerosis, dissection of the internal carotid or vertebral arteries or even vessels beyond the circle of Willis is a common source of embolic stroke.

Cardioembolic stroke

- Heart is a common source of emboli. Emboli from the heart **most often lodge in the middle cerebral artery (MCA)**, the **posterior cerebral artery (PCA)**, or one of their branches. Infrequently, the anterior cerebral artery (ACA) territory is involved.



Cerebral blood flow
mL/100 g/min
50
40
30
20
10
0
• Diffusion abnormality
• CBF <10 mL/100 g/min
• Cytotoxic edema
• Irreversible ischemia
Penumbra
• Perfusion abnormality
• CBF <10–18 mL/100 g/min
• Neuronal paralysis
• Reversible ischemia
Increase oxygen extraction
Failure of electrical function
Symptoms
Failure of ionic pumps
Potassium efflux
Sodium influx
Cell death

FIG. 16.10: Ischemic penumbra and ischemic core (black center).
(CBF: Cerebral blood flow)

- **Nonrheumatic atrial fibrillation** (and other arrhythmias) causing thrombosis in a dilated left atrium is the **most common cause of cerebral embolism**. Other causes include cardiac valvular disease such as congenital valve disorders, infective vegetations; rheumatic and degenerative calcific changes may cause embolization.
- Simultaneous infarcts in different vascular territories are suggestive that heart or aorta is the source of emboli.

Paradoxical embolus

Atrial septal defect or PFO may occasionally allow passage of fragments of thromboemboli [e.g., from a lower limb deep vein thrombosis (DVT)] from the right atrium to the left. This is believed to be the most common cause of cryptogenic strokes.

Other embolism like fat embolism, air embolism, amniotic fluid embolism, tumor embolism is rarely associated with neurological deficits.

Box 16.8: Etiology of ischemic stroke.

Thrombotic occlusion
- Small vessel (lacunar) stroke
- Large vessel thrombosis

Embolic occlusion
- **Artery-to-artery:** Carotid bifurcation, aortic arch, arterial dissection
- **Cardioembolic:** Atrial fibrillation, mural thrombus, myocardial infarction, dilated cardiomyopathy, valvular lesions, mitral stenosis, mechanical valve, bacterial endocarditis
- **Paradoxical embolus:** Atrial septal defect, patent foramen ovale

Venous sinus thrombosis

Subarachnoid hemorrhage due to vasospasm

Thrombosis occlusion

Large vessel thrombosis

Thrombosis developing at the site of ruptured mural atheromatous plaque may produce occlusion of involved vessel or may be a source of artery-to-artery embolism.

Small Vessel (Lacunar) Stroke

Q. Write a short essay/note on lacunar infarct.

- Small penetrating arterial branches of 200–800 µm in diameter, supply the deep brain parenchyma. Each of these small branches can be occluded either by atherothrombotic disease at its origin or by the development of occlusive vasculopathy—lipohyalinosis thickening (consequence of hypertension).
- Thrombosis of these vessels causes small infarcts that are referred to as lacunes. These infarcts range in size from **0.2 to 15 mm** in diameter.
- Risk factors include hypertension and age.
- Small vessel strokes account for 20% of all strokes.
- **Symptoms (Table 16.14):** Lacunar strokes present with fluctuating symptoms “capsular warning syndrome”.

TABLE 16.14: Signs and symptoms of lacunar stroke depending on location of lesion.

Syndrome	*Signs/symptoms*	*Localization*	*Vascular supply*
Pure motor	Contralateral hemiparesis or hemiplegia. Affects face, arm, and leg equally	➢ Posterior limb of internal capsule ➢ Corona radiata—basis pontis	Lenticulostriate branches of the middle cerebral artery (MCA) or perforating arteries from basilar artery
Pure sensory	Contralateral hemisensory loss. Persistent or transient numbness and/or tingling on one side of the body	Ventral posterolateral (VPL) nucleus of thalamus	Lenticulostriate branches of MCA. Small thalamoperforators of PCA (posterior cerebral artery)
Mixed sensorimotor	Contralateral weakness and numbness. Hemiparesis or hemiplegia with ipsilateral sensory impairment	Thalamus and adjacent posterior limb of internal capsule	Lenticulostriate branches of MCA
Dysarthria-clumsy hand	Slurred speech and weakness of contralateral hand (fine motor)	Basis pontis	Basilar artery perforators
Ataxic hemiparesis	Combination of cerebellar and motor symptoms. Contralateral hemiparesis and ataxia out of proportion to weakness	➢ Internal capsule—posterior limb ➢ Basis pontis ➢ Corona radiata	➢ Lenticulostriate branches of MCA ➢ Perforating arteries of basilar artery
Hemiballismus/ hemichorea	Contralesional limb flailing/dyskinesis	Subthalamic nucleus	Perforating arteries of anterior choroidal or posterior communicating artery (PCOM)

Q IM18.1 Describe the functional and the vascular anatomy of the brain.

Clinico-anatomic Correlation (Table 16.15)

TABLE 16.15: Features of cerebral ischemia depending on the neuroanatomic basis.

Vascular territory	*Signs and symptoms*
Internal carotid artery	➢ Combined ACA (anterior cerebral artery) + MCA (middle cerebral artery) ➢ Ipsilateral monocular visual loss (amaurosis) secondary to central retinal artery occlusion (CRAO)
Left ACA	➢ Right leg numbness and weakness ➢ Transcortical motor aphasia ➢ Ideomotor apraxia
Right ACA	➢ Left leg numbness and weakness ➢ Motor neglect ➢ Possibly ideomotor apraxia
Left MCA	➢ Right face/arm > leg numbness and weakness ➢ Aphasia ➢ Left gaze preference
Right MCA	➢ Left face/arm > leg numbness and weakness ➢ Left hemispatial neglect ➢ Right gaze preference ➢ Agraphesthesia/astereoagnosia

Stroke Localization—Clinical Features (Tables 16.16 to 16.18 and Fig. 16.11)

TABLE 16.16: Commmon localization of hemiplegia.

Site of lesion	*Predominant clinical features*
Cortex	➢ Monoplegia common (brachial—MCA territory; Crural—ACA territory) ➢ Hemiplegia (may be present but never dense) ➢ Contralateral VIIth cranial nerve palsy [upper motor neuron (UMN) variant] ➢ Seizures ➢ Aphasias (in dominant hemisphere) ➢ Apraxias (in nondominant hemisphere)
Subcortical (usually secondary to hypoperfusion)	➢ Monoplegias common ➢ Transcortical aphasias common
Internal capsule lesion	➢ Contralateral hemiplegia (dense) ➢ Contralateral hemisensory loss ➢ Contralateral VIIth cranial nerve palsy (UMN variant) ➢ Homonymous hemianopia ➢ Brocas's like aphasia (only site to have subcortical aphasia)
Note: Most common etiology being ischemic and hence is territory specific. Since different parts of internal capsule has blood supply from different blood vessels, all the above-mentioned features may not be present at same time. However, if present, it suggests hemorrhage or tumor compressing internal capsule.	

Contd...

Contd...

Site of lesion	*Predominant clinical features*
Brainstem lesion	Discussed separate **(Table 16.17)**
High cervical cord lesion (Brown–Sequard Syndrome)	➢ Ipsilateral hemiplegia ➢ Ipsilateral loss of posterior column sensation ➢ Contralateral loss of pain and temperature sensation ➢ Usually no cranial nerve involvement

TABLE 16.17: Posterior circulation strokes—brainstem syndromes.

Site of lesion/syndrome	*Blood supply and tracts involved*	*Ipsilateral (I/L) features*	*Contralateral (C/L) features*
Midbrain			
Benedikt's syndrome (Claude's + Weber's)	Interpeduncular branches of basilar artery, PCA—posterior cerebral artery (midbrain tegmentum—CN III fibers; red nucleus; CST; SCP)	Ipsilateral CN III palsy	Ataxia + Hyperkinesia and tremor (rubral tremor) + Hemiparesis
Claude's syndrome	PCA (midbrain tegmentum—CN III fibers; red nucleus; SCP)	Ipsilateral CN III palsy; contralateral	Ataxia + Tremor (rubral tremor)
Weber's syndrome	Paramedian branches of the basilar artery, PCA	Ipsilateral CN III palsy	Hemiparesis
Nothnagel's syndrome	Basilar penetrating artery, mesencephalic artery (midbrain tectum—ipsilateral or bilateral CN III)	Oculomotor palsies; ataxia	
Parinaud's syndrome	Midbrain dorsum (quadrigeminal plate region; pretectum; periaqueductal gray matter)	Impaired upgaze; convergence retraction nystagmus; dilated pupils with light-near dissociation	
Top of basilar artery syndrome	Midbrain Thalamus Portion of temporal and occipital lobe involved	Behavioral abnormalities Ocular finding Visual defects Pupillary abnormalities Motor deficits	
Artery of Percheron stroke	Single thalamic perforating artery from the proximal PCA	Altered sensorium vertical gaze palsy Memory impairment	
Pons			
Raymond–Céstan syndrome	Long circumferential branch of basilar artery (CN VI; CST)	VIth nerve palsy	Hemiparesis
Millard–Gubler syndrome	Basilar artery (CN VII; CST)	VIIth nerve palsy (± Lateral rectus palsy)	Hemiparesis
Foville's syndrome	Basilar artery (CN VII; lateral gaze center, CST)	VIIth nerve palsy + Horizontal gaze palsy	Hemiparesis
Pierre Marie–Foix syndrome	AICA	VIth + VIIth nerve palsy Horner's syndrome	Hemiparesis
Medulla			
Wallenberg's syndrome (lateral medullary syndrome)	Vertebral artery > posterior inferior cerebellar artery (PICA) (lateral medullary tegmentum—spinal tract of CN V and its nucleus; nucleus ambiguous; emerging fibers of CNs IX and X; LST; descending sympathetic fibers; vestibular nuclei; inferior cerebellar peduncle; afferent spinocerebellar tracts; lateral cuneate nucleus)	Loss of pain and temperature of face I/L decreased corneal reflex; I/L weakness of soft palate; I/L loss of gag reflex; I/L paralysis of vocal cord; I/L central Horner's syndrome; nystagmus; cerebellar ataxia of I/L limbs; lateropulsion; Hiccups	Loss of pain and temperature of body
Dejerine's syndrome (medial medullary syndrome)	Vertebral > anterior spinal artery	I/L tongue weakness	Hemiparesis
Avellis' syndrome	Medullary tegmentum	I/L palatal and vocal cord weakness	Loss of pain and temperature

Contd...

Contd...

Site of lesion/syndrome	***Blood supply and tracts involved***	***Ipsilateral (I/L) features***	***Contralateral (C/L) features***
Jackson's syndrome	Medullary tegmentum	Ipsilateral flaccid paralysis of soft palate, pharynx, and larynx; flaccid weakness and atrophy of SCM and trapezius (partial), and of the tongue	
Schmidt's syndrome	Lower medullary tegmentum	Ipsilateral paralysis of soft palate, pharynx, and larynx; flaccid weakness and atrophy of SCM and trapezius (partial)	
Céstan–Chenais syndrome	Due to vertebral artery occlusion below origin of the PICA (nucleus ambiguous; ICP; sympathetics; corticospinal tract, medial lemniscus)	Ipsilateral weakness of soft palate, pharynx, and larynx; cerebellar ataxia; Horner's syndrome	Contralateral hemiparesis with loss of posterior column function
Internuclear ophthalmoplegia (INO)	Medial longitudinal fasciculus (MLF) lesion in the midbrain	I/L adduction palsy	Contralateral gaze-evoked nystagmus
Wall-eyed bilateral internuclear ophthalmoplegia (WEBINO)	Bilateral MLF lesion in the brain	Bilateral adduction deficit and primary gaze position exotropia	
Gerstmann's syndrome	Parietal lobe	Inability to write (dysgraphia or agraphia), the loss of the ability to do mathematics (acalculia), the inability to identify one's own or another's fingers (finger agnosia), and inability to make the distinction between the right and left side of the body	
Anton's syndrome	Bilateral occipital cortex involvement due to bilateral PCA infarct	Anton's syndrome describes the condition in which patients deny their blindness despite objective evidence of visual loss, and moreover confabulate to support their stance	Anosognosia (or lack of awareness of defect) and confabulation
Balint's syndrome	Parieto-occipital lobes on both sides of the brain	Inability to perceive the visual field as a whole (simultanagnosia), difficulty in fixating the eyes (oculomotor apraxia), and inability to move the hand to a specific object by using vision (optic ataxia)	

TABLE 16.18: Clinical features of stroke depending on localization (anterior circulation).

Syndrome	***Clinical features***	***Localization***
Middle cerebral artery (M1) syndrome	Produces pure motor or sensory motor stroke contralateral to the side of lesion. If ischemia of putamen, pallidus—predominantly parkinsonian features	Internal capsule, caudate nucleus, putamen, and outer pallidus
Middle cerebral artery (M2) syndrome	Brachial syndrome: Weakness of hand and arm; Frontal opercular syndrome: Broca's aphasia with facial weakness with or without arm weakness	Superior division of MCA-M2 involved
	If dominant hemisphere: Wernicke's aphasia without weakness with contralateral homonymous superior quadrantanopia If nondominant hemisphere: Hemispatial neglect, spatial agnosia without weakness	Inferior division of MCA-M2 involved
Complete MCA syndrome	Contralateral hemiplegia, contralateral hemianesthesia, contralateral homonymous hemianopia, gaze preference to the ipsilateral side. If dominant hemisphere involved—global aphasia. If nondominant hemisphere involved—hemispatial neglect, anosognosia and constructional apraxia	
Unpaired ACA syndrome	Profound abulia and bilateral pyramidal signs with paraparesis or quadriparesis and urinary incontinence	Frontal lobe, entire medial part of cerebral hemispheres
Anterior choroidal artery occlusion syndrome	Contralateral (C/L) hemiplegia, C/L hemianesthesia, C/L homonymous hemianopia	Posterior limb of internal capsule, retrolentiform and sublentiform parts

• Hiccups
• No hemiplegia

FIG. 16.11: Localization of lesion in hemiplegia.

Lateral Medullary Syndrome

Q. Write a short note on lateral medullary syndrome.

It is also known as Wallenberg's syndrome and is due to occlusion of the **posterior inferior cerebellar artery or vertebral artery.** Localization/ structures involved and associated symptoms are presented in **Table 16.19**.

The trial of ORG 10172 in acute stroke treatment (TOAST) classification of subtypes of acute ischemic stroke is presented in **Box 16.9**.

Box 16.9: TOAST classification of subtypes of acute ischemic stroke.

- Large artery atherosclerosis
- Cardioembolism
- Small vessel occlusion
- Stroke of other determined etiology
- Stroke of undetermined etiology

Hypoperfusion and its consequences

- A **generalized reduction in CBF due to systemic hypotension** (e.g., cardiac arrhythmia, cardiac arrest, myocardial infarction, or hemorrhagic shock) usually **produces syncope**.

TABLE 16.19: Localization/structures involved and associated symptoms of lateral medullary syndrome (LMS).

Localization/structures involved	*Symptoms*
➢ Vestibular nuclei and connections ➢ Inferior cerebellar peduncle (Restiform body)	➢ Dizziness and imbalance ➢ Hypotonia ipsilateral side ➢ Diplopia/Oscillopsia ➢ Nystagmus, limb ataxia
➢ Spinal nucleus of CN V ➢ Spinothalamic tract	➢ Loss of pain and temperature sensation in ipsilateral face ➢ Loss of pain and temperature contralateral trunk (crossed sensory loss)
➢ Nucleus ambiguous (CN IX and X)	➢ Ipsilateral paralysis of palate, pharynx, and larynx ➢ Absent gag reflex
➢ Descending sympathetic fibers ➢ Dorsol motor nucleus of vagus	➢ Ipsilateral Horner's syndrome ➢ Autonomic signs—labile BP/ tachycardia/ sweating/arrhythmias
➢ Ventrolateral medullary tegmentum and the medullary reticular zone (respiratory centers)	➢ Failure of automatic respirations ➢ Hiccoughs
➢ **Corticospinal tracts, medial lemniscus not involved**	➢ **No pyramidal tract signs. Posterior column sensations preserved**

Oxfordshire Community Stroke Project (OCSP)—Bamford classification:

- **Total anterior circulation syndrome (TACS)**
  Hemianopia, hemiparesis, and higher cortical dysfunction
- **Partial anterior circulation syndrome (PACS)**
  Any two of TACS criteria or isolated higher cortical dysfunction
- **Lacunar syndrome (LACS)**
  Pure motor, pure sensory, sensorimotor strokes, dysarthria-clumsy hand syndrome or ataxic hemiparesis
- **Posterior circulation syndrome (POCS)**
  Isolated hemianopia or brainstem or cerebellar signs

- If low CBF persists for a longer duration, then **infarction in the border zones** (watershed areas) between the major and PCA distributions may develop (particularly if there is severe stenosis of proximal carotid vessels).
- In **more severe instances, global hypoxia-ischemia causes** widespread brain injury, the constellation of cognitive sequelae that ensues is called **hypoxic-ischemic encephalopathy**.
- **Focal ischemia or infarction**, conversely, is usually by thrombosis of the cerebral vessels themselves or by emboli from a proximal arterial source of the heart.

Carotid and vertebral artery dissection

- About 20% of cases of young (below the age 40 years) stroke are due to dissection of carotid or vertebral artery.
- It may develop sometimes as a **sequel of trivial neck trauma or hyperextension** (e.g., after whiplash, hair washing at a salon, or exercise). Predisposing factors include subtle collagen disorders (e.g., partial forms of Marfan's syndrome).
- **Most dissections occur in large extracranial neck vessels** and are characterized by **penetration of blood into the subintimal region of vessel wall** and form false lumen. However, it is the thrombosis within the true lumen due to tissue thromboplastin release which results in embolization from the site of dissection. This type of stroke sometimes develops days after the initial event.
- **Symptoms:** Pain in the neck or face is the clue for diagnosis.

Venous stroke

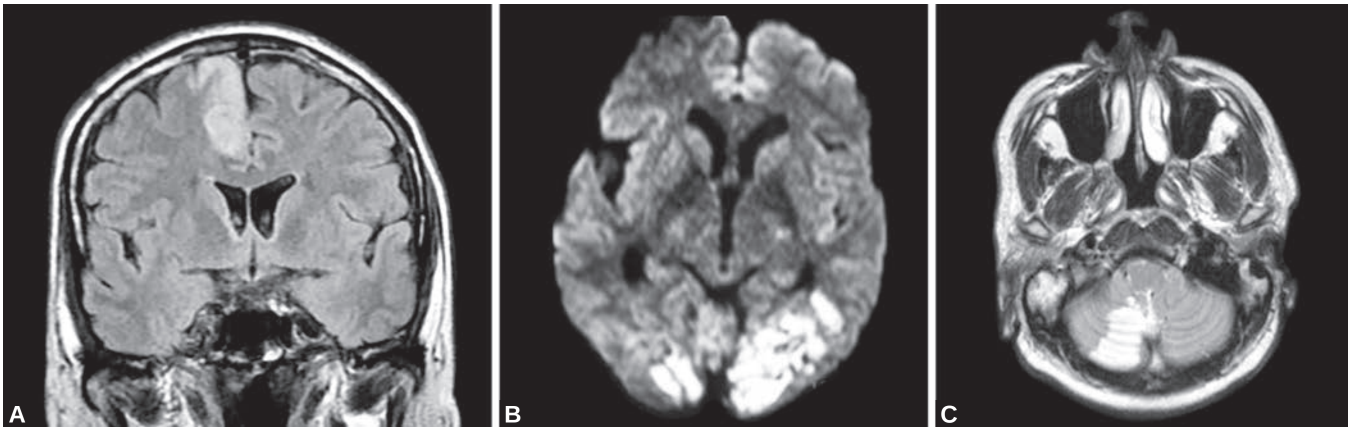
- Only 1% of strokes are due to venous thrombosis (within intracranial venous sinuses).
- **Predisposing factors:** It may occur in **pregnancy, hypercoagulable states** and thrombotic disorders or with dehydration or malignancy.
- **Consequences:** Cortical infarction, seizures, and raised ICP.

Investigations/Diagnosis

Q IM18.9 Choose and interpret the appropriate diagnostic and imaging test that will delineate the anatomy and underlying cause of the lesion.

Neuroimaging (Figs. 16.12A to C)

- **CT scans:** To identify or exclude hemorrhage as the cause of stroke.
    - They **identify extraparenchymal hemorrhage,** neoplasms, abscesses, and other conditions mimicking as stroke.
    - Brain CT scans in the first several hours after an infarction generally does not show any abnormality, and the infarct may not be detected reliably for 24–48 hours.
    - CT may fail to show small ischemic strokes in the posterior fossa because of bone artifact; small infarcts on the cortical surface may also be missed.
- **Magnetic resonance imaging (MRI):** Reliably documents the extent and location of infarction in all areas of the brain, including the posterior fossa and cortical surface. MRI is less sensitive than CT in detecting acute bleeding.
- **Diffusion-weighted imaging and FLAIR** (fluid-attenuated inversion recovery) imaging are more sensitive for early brain infarction than standard MR sequences or CT. It can identify ischemic penumbra and patients showing large regions of mismatch may be better candidates for acute revascularization.



FIGS. 16.12A TO C: Neuroimaging in stroke: (A) Acute right anterior cerebral artery (ACA) infarct; (B) Acute bilateral posterior cerebral artery (PCA) infarct—Anton's syndrome; (C) Right lateral medullary syndrome.

Vascular imaging

- Many ischemic strokes are due to atherosclerotic thromboembolic disease of the major extracranial vessels. Detection of extracranial vascular disease can establish the diagnosis of ischemic stroke and, it may also help for specific treatments (e.g., carotid endarterectomy to reduce the risk of further stroke).
- Extracranial arterial disease can be noninvasively detected by duplex ultrasound, magnetic resonance angiography (MRA) or CT angiography, or occasionally intra-arterial contrast radiography.

Cardiac investigations

- Cardioembolism is responsible for 20% of ischemic strokes. The source of emboli includes atrial fibrillation, prosthetic heart valves, other valvular abnormalities, and recent myocardial infarction.
- Clinical examination and ECG help in identifying the source of cardiac emboli. However, it may be necessary to perform a transthoracic or transesophageal echocardiogram to confirm the cardiac source or for detecting an unsuspected source (e.g., endocarditis, atrial myxoma, intracardiac thrombus or PFO). Such findings will help in providing specific cardiac treatment.

Blood investigations

- Complete blood count, erythrocyte sedimentation rate (ESR), glucose, renal function test (RFT), liver function test (LFT), serum electrolytes, prothrombin time-international normalized ratio (PT-INR), activated partial thromboplastin time (aPTT)
- **Workup for hypercoagulable states.**

- CBC with differential and platelets
- PT/aPTT
- Fibrinogen
- Factor VIII
- Factor VII
- C-reactive protein
- Antithrombin III
- Protein C
- Protein S (total and free)
- Lipoprotein (a)
- Activated protein C resistance (APCR)
- Leiden factor V mutation if APCR negative
- Prothrombin G20210A mutation
- Antiphospholipid antibodies (Abs)
  - Lupus anticoagulant
  - Anticardiolipin Abs
  - Anti-β-2-glycoprotein I Abs
  - Antiphosphatidylserine Abs
- Methyl tetrahydrofolate reductase
  - MTHFR C677T and A1298C mutations
- Sickle cell screen

Paramedical personnel and general public are taught how to make the diagnosis of stroke on a simple history and examination—**FAST (Box 16.10)**.

Box 16.10: Diagnosis of stroke on a simple history and examination—FAST.

- **F**ace: Sudden weakness of the face
- **A**rm: Sudden weakness of one or both arms
- **S**peech: Difficulty in speaking, slurred speech
- **T**ime: Sooner the starting of treatment, better the outcome

Complications of Acute Stroke (Box 16.11).

Q. Write a short essay/note on complications of stroke.

Differential Diagnosis of Stroke

See **Box 16.12.**

Box 16.11: Complications of acute stroke.

- Cerebral edema
- Cardiac arrhythmias, myocardial infarction, and neurogenic cardiac injury
- Chest infection
- Seizures
- Deep venous thrombosis/pulmonary embolism
- Pressure sores
- Urinary infection
- **GI bleed:** Stress ulcers, drug induced
- Constipation
- Painful shoulder/contractures
- Depression and anxiety
- Increased ICT and coning

Box 16.12: Differential diagnosis of stroke.

Structural stroke mimickers

- **Tumors:** Primary and metastatic cerebral tumors
- Subdural hematoma
- Cerebral abscess
- **Demyelinating disorders:** Multiple sclerosis
- Peripheral nerve lesions (vascular or compressive)

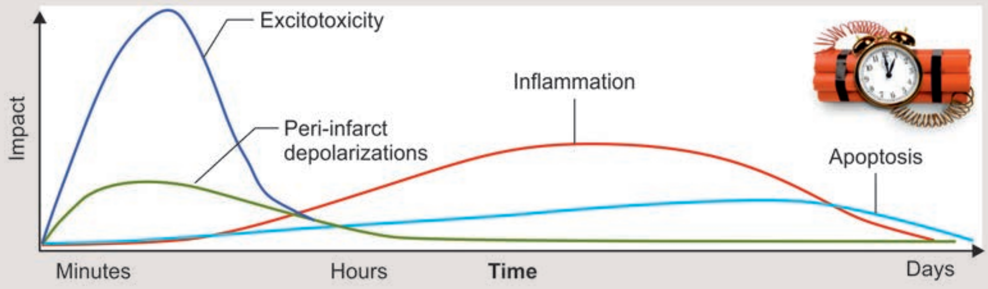
Functional stroke mimickers

- Seizure and postictal state
- Focal seizures
- Syncope
- Hypoglycemia
- Migrainous aura
- Conversion disorders and other psychiatric disorders
- Ménière's disease/other vestibular disorders
- Encephalitis
- Wernicke's encephalopathy
- Transient global amnesia
- Metabolic encephalopathy

Q. IM18.11 Describe the initial supportive management of a patient presenting with a cerebrovascular accident (CVA).

Treatment of Ischemic Stroke—"Time is Brain" (Fig. 16.13)

Treatments designed to reverse or lessen the amount of tissue infarction and improve clinical outcome fall into six categories: (1) IV thrombolysis, (2) endovascular techniques, (3) antithrombotic treatment, (4) medical support, (5) neuroprotection, and (6) stroke centers and rehabilitation.



Estimated pace of neural circuitry loss in typical large-vessel supratentorial acute ischemic stroke

	Neurons lost	Synapses lost	Myelinated fibers lost	Accelerated aging
Per stroke	1.2 billion	8.3 trillion	7,140 km	36 y
Per hour	120 million	830 billion	714 km	3.6 y
Per minute	1.9 million	14 billion	12 km	3.1 wk
Per second	32,000	230 million	200 m	8.7 h

FIG. 16.13: Treatment of ischemic stroke—"Time is brain".

1. **Intravenous thrombolysis**

Q. IM18.12 Enumerate the indications and describe acute therapy of nonhemorrhagic stroke including the use of thrombolytic agents.

- Intravenous (IV) administration for recombinant tissue plasminogen activator (r-tPA) within 3 hours of the onset of symptoms reduces disability and mortality from ischemic stroke.
  - Indications and contraindications for r-tPA **(Box 16.13)**.
- Administration
  - Administer at the rate of 0.9 mg/kg intravenously (maximum 90 mg) as 10% of total dose as an IV bolus and remainder of dose as a continuous IV infusion over 60 minutes.

Box 16.13: Indications and contraindications for recombinant tissue plasminogen activator (r-tPA).

Indications for r-Tpa

- Clinical diagnosis of stroke
- Onset of symptom to time of drug administration ≤3 hours (time window: 3–4.5 hours)
- Age ≥18 years
- CT scan showing no hemorrhage or infarct size >1/3rd of the middle cerebral artery (MCA) territory
- Consent by patient or surrogate

Contraindications for r-tPA

- Sustained BP >185/110 mm of Hg despite treatment
- Platelets <100,000/μL
- Hematocrit <25%
- Glucose <50 or >400 mg%
- Use of heparin/warfarin within 48 hours and prolonged activated partial thromboplastin time (aPTT) or international normalized ratio (INR)
- Prior intracranial hemorrhage
- Prior stroke or head injury within 3 months
- Major surgery in preceding 14 days
- Minor stroke symptoms
- GI bleed in preceding 21 days
- Recent myocardial infarction (within 3 months)
- Coma or stupor
- Pregnancy
- Age >80 years

        - No other antithrombotic treatment for 24 hours.
        - Avoid urethral catheterization for 2 hours.
    - For decline in neurologic status or uncontrolled blood pressure, stop infusion, give cryoprecipitate, and reimage brain emergently.
2. **Endovascular mechanical thrombectomy:** It is an alternative or adjunctive treatment of acute stroke in patients who are ineligible for, or have contraindications to, thrombolytics or in those who have failed to have vascular recanalization with IV thrombolytics.
3. **Antiplatelet therapy**

Q. IM18.13 Enumerate the indications and describe the role of antiplatelet agents in nonhemorrhagic stroke.

- *Platelet inhibition:* Aspirin 150 mg + clopidogrel 75 mg daily. *Note:* Glycoprotein IIb/IIIa receptor inhibitor abciximab causes excess ICH and should be avoided in acute stroke.
- Randomized studies of unfractionated heparin, low-molecular-weight heparins, or heparinoids have shown no proven benefits in the reduction of stroke-related mortality, stroke-related morbidity, early stroke recurrence, or stroke prognosis except in the case of cerebral venous thrombosis (CVT).

4. **Anticoagulation for acute ischemic stroke: Routine use of anticoagulation for acute ischemic stroke is not recommended.** Only indications for anticoagulants are:
    - Conditions with potential high risk of early cardiogenic re-embolization (e.g., atrial fibrillation)
    - Symptomatic arteriosclerotic stenosis with crescendo TIAs
    - Known hypercoagulable states
    - Cerebral venous sinus thrombosis.
5. **Medical support**
    - **Prevention of the common complications of bedridden patients:**
        - Infections (pneumonia, urinary, and skin): Prophylactic antibiotic.
        - Deep venous thrombosis with pulmonary embolism: Subcutaneous heparin and pneumatic compression stockings to prevent DVT.
        - Others: Catheterization, Ryle's tube (RT) feeding, maintenance of hygiene, etc.
    - **Maintenance of blood pressure:** Collateral blood flow within the ischemic brain is dependent on the blood pressure; hence, it is to be maintained.
        - Treat if BP >220/120 mm Hg.
        - BP goals in the first 24–48 hours poststroke:
            - No IV tPA: <220/120 mm Hg
            - IV tPA: <185/110 mm Hg.
        - First-line agents—labetalol, nicardipine, and clevidipine; second-line agent—nitroprusside [if diastolic blood pressure (DBP) >120 mm Hg].

          Avoid excessive lowering of BP just to give t-PA—"Do not kill the penumbra to save the penumbra".
        - Do not use antihypertensive drug except—left ventricular failure, aortic dissection, acute myocardial infarction, acute renal failure, and hypertensive encephalopathy.
    - **Fever:** It is detrimental and should be treated with antipyretics and surface cooling.
    - **Serum glucose** should be monitored and kept at <6.1 mmol/L (110 mg/dL) using an insulin infusion if necessary.
    - **Decreasing intracranial tension (ICT):** By water restriction and IV mannitol, oral glycerol, head end elevation.

      Hemicraniectomy (craniotomy and temporary removal of part of the skull) markedly reduces mortality.
        - People with MCA infarction who meet all of the criteria below should be considered for **decompressive hemicraniectomy.**
        - They should be referred within 24 hours of onset of symptoms and treated within a maximum of 48 hours:
            - Aged 60 years or under
            - Clinical deficits suggestive of infarction in the territory of the MCA with a score on the National Institute of Health Stroke Scale (NIHSS) of above 15
            - Decrease in the level of consciousness to give a score of 1 or more on item 1a of the NIHSS
            - Signs on MRI of an infarct of at least 50% of the MCA territory, with or without additional
            - Infarction in the territory of the anterior or PCA on the same side, or
            - Infarct volume >145 cm^3 as shown on diffusion-weighted MRI.
    - **Control of intracranial pressure:** In cerebellar strokes, even small amounts of cerebellar edema can acutely increase ICP or directly compress the brainstem. Prophylactic suboccipital decompression of large cerebellar infarcts before brainstem compression is very useful.

      Endovascular treatment approaches:
        - EKOS (ultrasound-enhanced thrombolysis)
        - Neuroflo (perfusion augmentation)
        - Mechanical endovascular thrombectomy

6. **Statins:** Atorvastatin (20–40 mg), rosuvastatin (10–20 mg)
7. **Neuroprotection:** Drugs that block the excitatory amino acid pathways (nimodipine, magnesium, lubeluzole, basic fibroblast growth factor, and citicoline) protect neurons and glia in animals, but they have not yet been proven to be beneficial in humans.
8. **Rehabilitation:**
   - Proper rehabilitation of the stroke patient includes early physical, occupational, and speech therapy. It is directed toward educating the patient and family about the patients' neurologic deficit, preventing the complications of immobility (e.g., pneumonia, DVT and pulmonary embolism, pressure sores of the skin, and muscle contractures), and providing encouragement and instructions in overcoming the deficit.
   - Goal of rehabilitation: It is to return the patient to home and to maximize recovery. The use of restraint therapy (immobilizing the unaffected side) has been shown to improve hemiparesis following stroke, even years following the stroke.

Secondary Prevention of Stroke and Transient Ischemic Attack

ABCD² score can help in identifying the stroke risk. A score of <4 is associated with a minimal risk whereas >6 is high risk for a stroke **(Table 16.20)**.

Treatment of Atherosclerosis

- **Risk factors:** Treatment of hypertension, diabetes, dyslipidemia, and cessation of smoking. Patients with higher risk scores need to be on anticoagulation while those with lower scores antiplatelet agents would suffice.
- **Atorvastatin:** In the dose of 80 mg/day useful both in secondary and primary prevention even with normal lipid levels.
- **Antiplatelet agents:** Aspirin, clopidogrel or dipyridamole are used.
- **Anticoagulation therapy for embolic stroke:** Anticoagulation (INR range, 2–3) in patients with chronic nonvalvular (nonrheumatic) atrial fibrillation prevents cerebral embolism and is safe. Warfarin, apixaban, dabigatran, rivaroxaban, edoxaban are equally effective.
- **Calculation of CHADS² score:** *One point for age > 75 years, one point for hypertension, one point for congestive heart failure (CHF), one point for diabetes, and two points for stroke or TIA; sum of points is the total CHADS² score.*

Treatment of Carotid Atherosclerosis

- **High-grade stenosis of carotid artery:** Patient with recent symptomatic (within 2 weeks of symptoms) hemisphere ischemia, high-grade stenosis (>70%) in the appropriate internal carotid artery, and an institutional perioperative morbidity and mortality rate of 6% generally should undergo carotid endarterectomy.
- **Low-grade stenosis of carotid artery:** For asymptomatic stenosis and symptomatic low-grade stenosis (50–70%), medical therapy for reduction of atherosclerosis risk factors, including cholesterol-lowering agents and antiplatelet medications, is generally recommended.
- **Endovascular therapy:** Balloon angioplasty coupled with stenting to open stenotic carotid arteries and maintain their patency.

Treatment of Intracranial Atherosclerosis

- Symptomatic lesions with intracranial angioplasty and stenting.
- **Dural sinus thrombosis:** By short-term anticoagulants, regardless of the presence of ICH, for venous infarction following sinus thrombosis.

Young Stroke (Box 16.14)

Q. IM18.10 Choose and interpret the appropriate diagnostic testing in young patients with a cerebrovascular accident.

Q. Write a short essay/note on etiology of stroke in a young.

The term "young stroke" is used to denote stroke in individuals <45 years of age.

Intracranial Hemorrhage

Q. Describe the risk factors, etiopathogenesis, clinical features, investigations, diagnosis, and management of cerebral/intracerebral hemorrhage.

Q. Describe the etiology, clinical features, investigations, and management of hemorrhagic stroke.

TABLE 16.20: Features and ABCD² score useful in assessing the stroke risk.

Clinical feature	*Score*
A: Age >60 years	1
B: BP systolic >140 mm Hg or diastolic BP >90 mm Hg	1
C: Clinical symptoms	
➢ Unilateral weakness	2
➢ Speech disturbance without weakness	1
D: Duration of symptoms	
> 60 minutes	2
10–59 minutes	1
D: Diabetes (oral medications or insulin)	1
ABCD² total score	Sum each category

Box 16.14: Causes for young stroke.

- **Cardiac**
  - Congenital heart disease, patent foramen ovale
  - Atrial myxoma
  - Atrial fibrillation and other arrhythmia
  - Cardiomyopathy, myocarditis, myocardial infarction
  - Cardiac surgery, cardiac catheterization
  - Endocarditis, rheumatic heart disease
  - Prosthetic valve
- **Hematologic**
  - Sickle cell disease, iron deficiency anemias, polycythemia vera
- **Hypercoagulable states**
  - Inherited prothrombotic states, protein C and S deficiency, antithrombin III deficiency, factor V Leiden gene mutation, prothrombin gene mutation
  - Antiphospholipid syndrome
  - Hyperhomocysteinemia
  - Myeloproliferative disorders (e.g., leukemia, lymphoma)
  - Pregnancy
  - Exposure to hormonal treatments such as anabolic steroids and erythropoietin
  - Nephrotic syndrome
- **Vascular**
  - **Noninflammatory**
    - Arterial dissection
    - Secondary to connective tissue disease (Ehlers–Danlos, Marfan)
    - Moyamoya disease
    - Hypertension
    - Radiation vasculopathy
    - Vasculitis and postinfectious vasculopathy
    - Migraine
    - Cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL) Fibromuscular dysplasia, Susac's syndrome, Sneddon's syndrome, Fabry's disease
  - **Inflammatory**
    - Takayasu arteritis
    - Giant cell arteritis
    - Kawasaki disease
    - Polyarteritis nodosa
    - Human immunodeficiency virus (HIV)
    - Bacterial meningitis

- This includes: (1) intracerebral **(Fig. 16.14)** and cerebellar hemorrhage, (2) subarachnoid hemorrhage (SAH), and (3) subdural and extradural hemorrhage/hematoma.
- It causes about 10% of acute stroke events. It is usually due to rupture of a blood vessel within the brain parenchyma but may also occur in association with an SAH if the artery ruptures into the brain substance as well as into the subarachnoid space.
- **Hypertensive intraparenchymal hemorrhage** (hypertensive hemorrhage or hypertensive intracerebral hemorrhage) usually results from spontaneous rupture of a small penetrating artery deep in the brain. The most common sites are the **basal ganglia (especially the putamen), thalamus, cerebellum, and pons. Cortical bleeds are rare.**
- **Pontine hemorrhages:** 3Ps namely pinpoint pupil, hyperpyrexia, paralysis (quadriplegia). There is prominent decerebrate rigidity and "pinpoint" (1 mm) pupils that react to light. There is impairment of reflex horizontal eye movements evoked by head turning (doll's head or oculocephalic maneuver) or by irrigation of the ears with ice water.

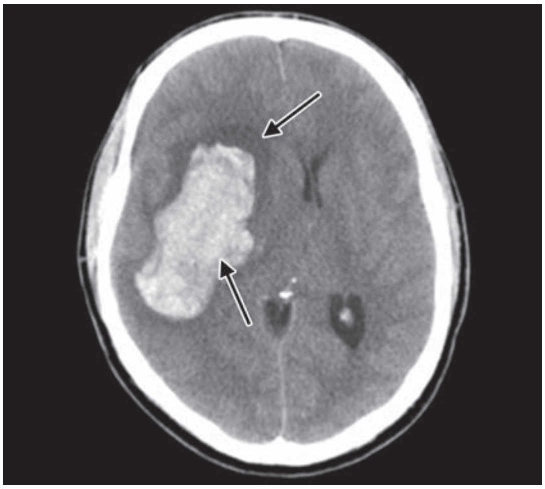


FIG. 16.14: CT showing hemorrhage in internal capsule.

- **Primary versus secondary hemorrhage** (hemorrhage that frequently occurs also into an area of brain infarction)—may be difficult to distinguish from primary intracerebral hemorrhage both clinically and radiologically.

Consequences of Hemorrhage

- **Immediate cessation of function:** The sudden entry of blood into the brain parenchyma causes immediate cessation of function in that area as neurons are structurally disrupted with splitting of white matter fiber tracts.
- **Mass effect:** The hemorrhage may expand over the first minutes or hours, or it may produce a rim of cerebral edema. Progression of neurological deficit occurs due to the mass effect. If large, they can cause shift of the intracranial contents, producing transtentorial coning and sometimes rapid death.

- **Resorption of hematoma:** If the patient survives, the hematoma is gradually absorbed, and produces a hemosiderin-lined slit in the brain parenchyma.

Causes of Intracranial Hemorrhage

See **Table 16.21.**

TABLE 16.21: Causes of intracranial hemorrhage and its location.

Cause	*Location*	*Comments*
Head trauma	Intraparenchymal: Frontal lobes, anterior temporal lobes, subarachnoid	Coup and countercoup injury during brain deceleration
Hypertensive hemorrhage	Putamen (most common), globus pallidus, thalamus, cerebellar hemisphere, pons	Chronic hypertension produces hemorrhage from small (100 μm) vessels in these regions
Metastatic brain tumor	Lobar	Primary tumors in lung, choriocarcinoma, melanoma
Coagulopathy	Any	Uncommon cause: Often associated with prior stroke or underlying vascular anomaly
Drug	Lobar, subarachnoid	Cocaine, amphetamine, phenylpropanolamine
Arteriovenous malformation	Lobar, intraventricular, subarachnoid	Risk is 2–4% per year for bleeding
Aneurysm	Subarachnoid, intraparenchymal, rarely subdural	Mycotic and nonmycotic forms of aneurysms
Cerebral amyloid angiopathy	Lobar	Most common cause for recurrent lobar hemorrhage in elderly

Clinical Features

- Clinical presentation depends upon which arterial territory is involved and the size of the lesion.
- **Rapid-onset:** Occurs over minutes.
- **Most common presentation:** Weakness of the face or arm, or disturbance of speech.
- **Focal deficit of brain function:** Affects an identifiable area of the brain and is "negative" in character (i.e., abrupt loss of function without positive features such as abnormal movement). Features which suggest the location of lesion are:
  - *Lesion in the cerebral hemisphere:* Usually characterized by unilateral motor deficit, a higher cerebral function deficit such as aphasia or neglect, or a visual field defect.
  - *Lesion in the brainstem or cerebellum:* Ataxia, diplopia, vertigo and/or bilateral weakness.
  - *Intracerebral hemorrhage:* Combination of severe headache and vomiting at the onset of the focal deficit.

Management/Treatment

Q. IM18.14 **Describe the initial management of a hemorrhagic stroke.**

Any identified coagulopathy should be reversed as soon as possible.

- For patients taking VKAs (vitamin K antagonists), rapid reversal of coagulopathy can be achieved by infusing prothrombin complex concentrates which can be administered quickly, followed by fresh frozen plasma and vitamin K.
- When ICH is associated with thrombocytopenia (platelet count <50,000/μL), transfusion of fresh platelets is indicated.

Control of BP

- BP >185/110 increases the size of hematoma by more bleeding. Hence, maintain a mean arterial pressure (MAP) <130 mm Hg, unless an increase in ICP is suspected.
- In patients who have ICP monitors in place, keep the cerebral perfusion pressure (MAP-ICP) >60 mm Hg (i.e., one should lower MAP to this target if blood pressure is elevated).
- Blood pressure should be lowered with nonvasodilating IV drugs such as nicardipine, labetalol, or esmolol.

Hyperosmolar therapy

- **Mannitol:** Bolus of 0.25 g/kg–1 g/kg body weight.
- Hypertonic saline, concentrations ranging from 3 to 23.4%.

Hyperventilation decreases $PaCO_2$, which can induce constriction of cerebral arteries by alkalinizing the cerebrospinal fluid (CSF).

Barbiturate coma

Pentobarbital is given in a loading dose of 10 mg/kg body weight followed by 5 mg/kg body weight each hour for three doses.

Hypothermia

Steroids are used for primary and metastatic brain tumors, to decrease vasogenic cerebral edema.

Treatment of raised intracranial tension

- If the hematoma causes marked midline shift of structures with consequent obtundation, coma or hydrocephalus, osmotic agents coupled with induced hyperventilation can be instituted to lower ICP.
- Once ICP is recorded, further hyperventilation and osmotic therapy can be tailored to the individual patient to keep cerebral perfusion pressure (MAP-ICP) above 60 mm Hg.

- If ICP is still found to be high, CSF can be drained from the ventricular space and osmotic therapy continued.
- Persistent or progressive elevation in ICP may prompt surgical evacuation of the clot.
- Glucocorticoids are not helpful for the edema from intracerebral hematoma.
- Most cerebellar hematomas >3 cm in diameter will require surgical evacuation.

Q. IM18.15 Enumerate the indications for surgery in a hemorrhagic stroke.

The different types of surgical treatment for hemorrhagic stroke are craniotomy, decompressive craniectomy, stereotactic aspiration, endoscopic aspiration, and catheter aspiration:

- Those who have lobar hemorrhages within 1 cm of the surface of the brain and milder clinical deficits (GCS >9) may benefit from early surgery.
- Emergency surgical evacuation is indicated in cerebellar hemorrhage with hydrocephalus or brainstem compression.Patients with cerebellar hemorrhages of >3 cm in diameter will have better outcomes with surgery. Cerebellar hematoma is evacuated by suboccipital craniectomy.
- Intracerebral hemorrhage surgery is probably indicated for patients with superficial spontaneous lobar supratentorial intracerebral hemorrhage (ICH) when the level of consciousness drops below Glasgow coma scale 13 within the first 8 hours of the onset of the hemorrhage.

Transient Ischemic Attack

Q. Write a short essay/note on TIA including its definition.

Transient ischemic attack is characterized by a brief episode of neurological dysfunction (sudden loss of function) in which symptoms and signs resolve completely after a brief period within 24 hours (usually within 30 minutes).

- Transient ischemic attack is defined as a transient episode of neurologic dysfunction caused by focal brain, spinal cord, or retinal ischemia, without acute infarction. However, TIAs may herald a stroke.
- It may be better to describe as symptoms <1 hour with no evidence of infarction.
- It may have infarct even with symptoms lasting a few hours (~50% of TIA patients have MRI evidence of ischemia).
- Newer, neuroimaging informed, operational definitions of TIA "a brief episode of neurological dysfunction caused by focal brain or retinal ischemia, with clinical symptoms typically lasting less than ***one hour, and without evidence of acute infarction".***

Clinical Features

Hemiparesis and aphasia are most common. Other features include amaurosis fugax (sudden transient loss of vision in one eye), hemisensory loss, hemianopic visual loss, diplopia, vertigo, vomiting, choking, dysarthria, ataxia, etc.

Types

Types of TIA have been shown in **Box 16.15**.

Box 16.15: Types of transient ischemic attack (TIA).

- Embolic TIA—recurrent, short-lasting episodes of stereotyped symptoms (shotgun TIA)
- Large artery TIA—longer-lasting less frequent episodes with varied symptoms
- Lacunar TIA

*Recurrent same side, same territory TIA is suggestive of vessel disease

*TIA in both anterior and posterior circulation is suggestive of cardioembolism

Diagnosis

Diagnosis of TIA often depends on its description. There may be clinical evidence of a source of embolus (e.g., carotid arterial bruit/stenosis, atrial fibrillation or other dysrhythmia, valvular heart disease/endocarditis, recent myocardial infarction).

An underlying **risk factor**/condition may be present. These include atheroma, hypertension, postural hypotension, bradycardia or low cardiac output, diabetes mellitus, etc.

Treatment (Flowchart 16.7)

Medical therapy and surgical treatment if appropriate. If patients have ABCD^2 (*refer* **Table 16.20**) score >4, or have had two recent TIAs (especially within the same vascular territory), they should be investigated and advised for secondary prevention of stroke.

Subarachnoid Hemorrhage

Q. Discuss the clinical manifestations and treatment of primary SAH.

Q. Write a short essay/note on SAH.

Subarachnoid hemorrhage is a pathologic condition in which the **blood enters the subarachnoid space.** SAH is less common than ischemic stroke or intracerebral hemorrhage. It accounts for about 5% of strokes.

FLOWCHART 16.7: Management of transient ischemic attack (TIA).

Etiology (Table 16.22)

- **Most common cause** of SAH **is trauma**.
- **Most common cause of spontaneous SAH** is an **aneurysmal** (saccular or "berry" aneurysms) **bleed** (65–80%).
- SAH causes intense reductions in CBF, reduced cerebral autoregulation, and acute cerebral ischemia.
- The overall case fatality varied from 32 to 67%.

TABLE 16.22: Causes of subarachnoid hemorrhage.

Category	*Causes*
Trauma	Closed, penetrating, electric, etc.
Vascular	Aneurysms (berry aneurysm), atherosclerosis, arteriovenous malformations (AVMs), vasculitides
Idiopathic	Benign peri mesencephalic subarachnoid hemorrhage
Blood dyscrasias	Leukemia, hemophilia, thrombocytopenia
Infections	Dengue, leptospirosis, bacterial meningitis
Toxins	Amphetamines, cocaine, nicotine, anticoagulants
Neoplasms	Gliomas, meningiomas, hemangioblastoma, etc.

Risk factors for SAH have been shown in **Box 16.16**.

Box 16.16: Risk factors for subarachnoid hemorrhage.

- Hypertension
- Cigarette smoking
- Oral contraceptives
- Diurnal variations in blood pressure
- Pregnancy and parturition
- Slight increased risk during lumbar puncture and/or cerebral angiography in patient with cerebral aneurysm
- Slight increased risk with advancing age
- Alcohol consumption (debatable)
- Following cocaine abuse
- Increased incidence of polycystic kidneys
- Fibromuscular dysplasia of extracranial arteries, Ehlers–Danlos syndrome, moyamoya, AV malformations and coarctation of aorta

Circle of Willis

- Circle of Willis is a circulatory anastomosis that supplies blood to the brain and surrounding structures. This anastomotic pathway is important for the preservation of brain function when major blood flow is disrupted in one of the major feeding vessels.
- Constituent arteries of the circle of Willis **(Fig. 16.15 and Box 16.17).**

  The MCAs, supplying the brain, do not form the part of the circle of Willis.

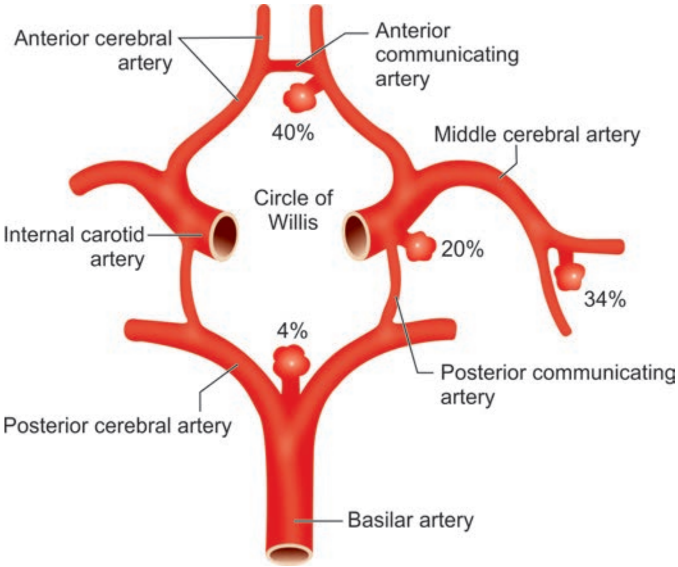

FIG. 16.15: Blood supply to the brain and circle of Willis with common sites of saccular (berry) aneurysms.

Saccular ("berry") aneurysm

- Saccular aneurysms develop within the circle of Willis and adjacent arteries. Three most common locations are—(1) the terminal internal carotid artery, (2) MCA bifurcation, and (3) top of the basilar artery.
- It can undergo spontaneous rupture and cause SAH. If the patient survives, but the aneurysm is not obliterated, the rate of rebleeding is about 20% in the first 2 weeks, 30% in the first month, and about 3% per year afterward.
- The annual risk of rupture for aneurysms <10 mm in size is 0.1%, and for aneurysms >10 mm in size is 0.5–1%.

Clinical Features of Subarachnoid Hemorrhage

- **Headache:** Most common symptom (97%). Usually severe (the worst headache of my life) and sudden **(thunderclap)** in onset. Few patients may have milder warning headaches (sentinel headaches) in 2–8 weeks preceding the major hemorrhage. Headache may pulsate toward the occiput and sometimes may be felt as neck pain. Occipital and posterior cervical pain may signal a posterior inferior cerebellar artery or anterior inferior cerebellar artery aneurysm. If there is expanding MCA aneurysm, pain may be observed in or behind the eye and in the low temple. Headache commonly occurs on physical exertion, straining, and sexual excitement.
- **Vomiting** may be present.
- **Other symptoms:** Decreased consciousness and alertness, seizure (10%) and stiff neck, etc.
- **Re-rupture/rebleed:** The re-rupture of an untreated aneurysm in the first month following SAH is ~30%, with the peak in the first 7 days.

Box 16.17: Constituents arteries of circle of Willis.

- Two internal carotid arteries (left and right)
- Anterior cerebral artery (left and right)
- Anterior communicating artery
- Posterior cerebral artery (left and right)
- Posterior communicating artery (left and right)
- Basilar artery formed by joining of two vertebral arteries

Physical examination

- Patient is usually distressed and irritable, with photophobia.
- Neck stiffness (and a positive Kernig's sign) due to subarachnoid blood may be present but this may take few hours to develop. Focal hemisphere signs (e.g., intracerebral hematoma may cause hemiparesis or aphasia).
- Rarely, IIIrd nerve palsy may be developing due to local pressure from an aneurysm of the posterior communicating artery.
- **Fundoscopy:** It may show **sub hyaloid hemorrhage** which is canoe-shaped, (***SAH plus sub hyaloid hemorrhage** = **Terson's syndrome***) produced due to tracking of blood along the subarachnoid space around the optic nerve.

Investigations

Computed tomography scan: It shows blood in the subarachnoid space (if performed in the first few days), intracerebral hematoma, hydrocephalus, associated brain ischemia, and occasionally aneurysmal location.

Q. Write a short essay/note on CSF findings in SAH.

- **Lumbar puncture:** It should be performed when clinical suspicion of SAH is high, CT scan does not reveal subarachnoid blood, and there is no mass effect. In the initial few hours, CSF will be uniformly blood stained. **Xanthochromia** appears within 6 hours of SAH and persists for nearly 2 weeks. Naked inspection of supernatant CSF is usually sufficiently reliable for diagnosis of SAH. Spectrophotometry to estimate bilirubin in the CSF released from lysed cells confirm the diagnosis.
- **Angiography:** It is required to locate the site of bled aneurysm and details that are needed to ligate the aneurysm by the neurosurgeon. It should be done in all patients fit for surgery (i.e., age <65 years and who are not in coma).
- **Magnetic resonance angiography:** It will accurately identify aneurysms > 5 mm in size.
- **CT angiography:** It is a rapid readily available, less invasive alternative to catheter angiography. It is equivalent to conventional angiography for detecting large aneurysms.
- **ECG changes:** Prolonged QRS complex, increased QT interval, and prominent "peaked" or deeply inverted symmetric T waves are usually secondary to the ICH **(cerebral T waves) (Fig. 16.16).**

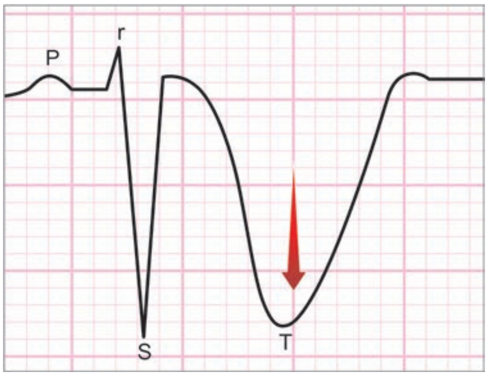

FIG. 16.16: Electrocardiographic (ECG) changes.

Differential Diagnosis of Subarachnoid Hemorrhage

See **Box 16.18**.

Box 16.18: Differential diagnosis of subarachnoid hemorrhage.

- Migraine
- Acute bacterial meningitis
- Cervical arterial dissection

Complications

- **Obstructive hydrocephalus:** Due to blood in the subarachnoid space. It may be asymptomatic but may cause deteriorating consciousness following SAH. Shunting may be required.
- **Arterial spasm (cause of coma or hemiparesis):** It is a serious complication and is a poor prognostic feature.
- Hyponatremia.

Q. Write a short essay/note on treatment of SAH.

Management

- Immediate treatment is absolute **bed rest** (for 4 weeks) and **supportive measures.** These include protecting the airway, managing blood pressure and raised ICP, treating seizures, pain management, and sedation. It should be discussed urgently with a neurosurgical team. Patient is advised to gradually resumption of physical activities after recovery.
- **Control of hypertension:** In conscious patients without raised ICP, active treatment of hypertension is necessary. A target MAP of 130 mm Hg is recommended. Drugs include labetalol, esmolol or nicardipine. Sodium nitroprusside should be avoided because may cause increase of ICP.
- **Avoid strictly:** *Hypovolemia, hypotension, hyperthermia, hyperglycemia, and hyponatremia*.
- **Calcium channel blocker:** Nimodipine (30–60 mg IV for 5–14 days, followed by 360 mg orally for a further 7 days) provides a modest but significant improvement in outcome by reducing cerebral arterial vasospasm. It is given for 3 weeks to prevent delayed ischemia in the acute phase and decreases mortality.
- **Prophylactic anticonvulsants**
- **Interventional management:** Early aneurysm repair prevents re rupture/rebleeding and improve blood flow. An aneurysm can be "clipped" by a neurosurgeon or "coiled" by an endovascular surgeon.
  - **Insertion of platinum coils into an aneurysm:** If angiography shows an aneurysm (most common cause of SAH), endovascular treatment by inserting a platinum coil via a catheter in the aneurysm sac to promote thrombosis and ablation of the aneurysm, is the first-line treatment. Surgical clipping of the aneurysm neck also helps in reducing the risk of recurrence (both early and late). Endovascular coiling has fewer perioperative complications and better outcomes than surgery. For unruptured aneurysms >8 mm in diameter the risk of treatment is less than the risk of hemorrhage if not treated.
- **Treatment of complications:** Managing delayed cerebral ischemia due to vasospasm (may be treated with vasodilators), treating obstructive hydrocephalus (may require drainage via a shunt), treating hyponatremia (managed by fluid restriction), and systemic complications associated with immobility, such as chest infection venous thrombosis and preventing pulmonary embolus.

Q. Identify the nature of the cerebrovascular accident based on the temporal evolution and resolution of the illness.

The differences between hemorrhagic, thrombotic, and embolic strokes are listed in **Table 16.23**.

TABLE 16.23: Differences between hemorrhagic, thrombotic, and embolic strokes.

Feature	*Hemorrhagic stroke (intracerebral or subarachnoid hemorrhage)*	*Ischemic stroke*	
		Thrombotic	*Embolic*
Time of onset of stroke	During activity	Suddenly and often during sleep or in the early morning (4 AM)	Any time
Rapidity of onset and progression	Over minutes and hours	On waking up or over hours	Rapid within seconds deficit maximum at onset
Transient ischemic attacks (TIAs)	Absent	Precedes stroke	Precedes stroke
Vomiting	Recurrent	Absent or occasional	Absent or occasional
Headache	Severe and prominent	Mild or absent	Mild or absent
Early resolution (within minutes or days)	Unusual	Variable	Possible
Meningeal irritation	May be present	Absent	Absent
Carotid bruit and absence of pulse	Not observed	Highly supports the diagnosis	Possible
Valvular heart disease and atrial fibrillation	Not found	Unusual	Highly supports the diagnosis
CT scan findings	Hemorrhage	Early stage: Normal; Later: Pale infarct	Early stage: Normal: Later Pale infarct

Note: It may not be possible always to differentiate stroke of different type with absolute certainly.

Cerebral Venous Thrombosis

Q. Write a short note on cerebral venous thrombosis.

It is the thrombosis of the draining venous sinuses of the cerebral cortex and the least common of all other types of cerebrovascular accidents (1–2% of strokes in young adults).

Thrombosis most commonly involves superior sagittal sinus and it may extend into transverse and sigmoid sinuses. Thrombosis of deep venous system (e.g., internal cerebral veins, vein of Galen or straight sinus) is less common.

Age and gender: It frequently affects young adults and children. More common in women than men with an F:M ratio of 3:1. It may be due to the presence of gender-specific risk factors such as pregnancy, puerperium, oral contraceptive pills, and hormone replacement therapy (HRT). One of the leading causes of maternal mortality and morbidity with cases of puerperal CVT occurring 10–12 times more frequently in India than the west.

Causes of Cerebral Venous Thrombosis

See **Table 16.24.**

TABLE 16.24: Causes of cerebral venous thrombosis (CVT).

Local causes	*Systemic causes*
➢ Trauma to the dural sinuses ➢ Infection of structures adjacent to the dural sinuses: Otitis media, mastoiditis, sinusitis, tonsillitis ➢ Invasion or compression of venous sinuses by neoplasms	**Hypercoagulable states** (e.g., inherited prothrombotic states, protein C/S deficiency, antithrombin III deficiency, factor V Leiden gene mutation, prothrombin gene mutation, presence of lupus anticoagulant, oral contraceptive use, pregnancy, malignancy), dehydration

Pathophysiology

Two basic mechanisms are responsible for the development of the clinical features in CVT:

1. Thrombosis of cerebral veins or sinuses leading to cerebral parenchymal lesions or dysfunctions.
2. Occlusion of dural venous sinus causes reduced absorption of CSF and raised ICP.

Obstruction of venous structures → increased venous pressure → decreased capillary perfusion → increased cerebral blood volume → disruption of blood brain barrier → plasma leakage into interstitial space → cerebral edema, parenchymal changes, and venous hemorrhage.

Clinical Features

The clinical presentation of CVT is highly variable and it may present as acute/subacute/chronic.

Symptoms and signs: Depends on the sinuses involved, the place of occlusion, and involvement of cortical veins and presence of collaterals, parenchymal changes and the patient's age. Symptoms are grouped under three major clinical syndromes:

1. **Isolated intracranial hypertension syndrome** (headache with or without vomiting, papilledema, and visual problems)
2. **Focal syndrome** (focal deficits or seizures or both)
3. **Encephalopathy** (multifocal signs, mental status changes, stupor, or coma).

Diagnosis

- **CT or MR venography:** Direct signs of CVT in CT include:
  - *Dense triangle sign*—seen as hyper density with triangular shape at the posterior end of superior sagittal sinus caused by venous thrombus.
  - *Empty delta sign*—seen in head CT with contrast as a triangular pattern of contrast enhancement surrounding a central region lacking contrast enhancement.
  - *Cord sign*—as linear or curvilinear hyper density over the cerebral cortex caused by thrombosed cerebral veins.
- **CT or MRI** to detect secondary parenchymal lesions.
- **CSF examination:** To rule out meningitis or SAH.
- Workup for prothrombotic state.

Treatment

Treatment should be started as soon as the diagnosis is confirmed and consists of:

- Treatment of the underlying cause when known.
- Control of seizures and intracranial hypertension.
- **Antithrombotic therapy.**

The main treatment option to achieve these goals is anticoagulation using heparin or LMWH (IV/SC). It is recommended that anticoagulant therapy with warfarin should be given for a minimum of 3 months after acute CVT aiming at an INR target of 2.5 (2–3).

DEMYELINATING DISEASES

Q. What are the common demyelinating diseases?

Table 16.25 shows examples of demyelinating diseases.

Multiple Sclerosis

Q. Write a short essay on multiple sclerosis (MS) and its clinical features.

- Chronic autoimmune T-cell-mediated inflammatory disorder with selective destruction of myelin of the central nervous system (CNS). It has a **relapsing-remitting** or progressive course. The neurological deficits are disseminated in time and space.
- It is termed multiple sclerosis because of the multiple scarred areas (well-demarcated gray areas termed **plaques)** of demyelination throughout the brain and spinal cord observed on macroscopic examination. The plaques are crucial for diagnosis. The peripheral nervous system (PNS) is generally spared.

TABLE 16.25: Example of demyelinating diseases.

Central nervous system	*Peripheral nervous system*
➢ **Autoimmune** [e.g., multiple sclerosis (MS), neuromyelitis optica]	➢ Deficiencies of vitamin B_1: Dry beriberi
➢ **Nutritional** (e.g., Wernicke's encephalopathy, subacute combined degeneration)	➢ Guillain–Barré syndrome
➢ **Infectious** [e.g., acute disseminated encephalomyelitis (ADEM), HIV encephalitis, Creutzfeldt–Jakob encephalitis]	➢ Vitamin B_{12} deficiency ➢ Organophosphate poisoning ➢ Chronic inflammatory demyelinating polyneuropathy
➢ **Toxic** (e.g., radiation, chemotherapeutic agents, methanol)	➢ Charcot–Marie–Tooth disease ➢ Copper deficiency
➢ **Hypoxic/ischemic** (e.g., vasculitis)	

Epidemiology

- **Gender:** Female preponderance and female to male ratio is 2:1.
- **Age:** Usually present between 20 and 40 years of age and is rare after 60 years of age.

Pathophysiology

Both genetic and environmental factors play a causative role.

- **Genetic factors:** Risk of familial recurrence in MS is 15%, with highest risk in first-degree relatives. Multiple genes interact and it has a complex polygenic inheritance pattern. HLA-DR2 association. Other autoimmune disorders occur in patients with MS and their relatives, indicating a genetic predisposition to autoimmunity.
- **Environmental factors:** Epidemiologic evidence supports the role of an environment exposure in MS but these factors are still largely unknown [e.g., sunlight exposure, vitamin D, and exposure to Epstein–Barr virus (EBV)]. Viral infections can precipitate MS relapses in genetically susceptible individuals.

Etiology and Pathogenesis

- Etiology is not known.
- It is probably a T-cell-mediated autoimmune disease causing an inflammatory process within the white matter of the brain and spinal cord. MS risk correlates with high socioeconomic status, which may reflect improved sanitation and delayed initial exposures to infectious agents.

Clinical Manifestations

- No single group of signs or symptoms is diagnostic of MS **(Table 16.26)**.
- **Onset:** May be abrupt/insidious, vary from trivial to severe form.
- Presentation varies and depends on the anatomical site of lesions and severity. It has been called as the modern "great imitator". MS commonly involves ***pyramidal tract, optic nerve, posterior cord, cerebellum, and medial longitudinal fasciculus (MLF).***
- **Common symptoms in MS (Box 16.19):** Disability and neurological impairments gradually accumulate over the years.

Clinical course: Main clinical patterns are:

- **Relapsing-remitting MS** (RRMS) (85–90%): Discrete attack and complete recovery.
- **Secondary progressive MS** (SPMS): Begin as RRMS, clinical steady deterioration at some stage.
- **Primary progressive MS** (PPMS) (10–15%): Steady function decline from onset.
- Progressive relapsing MS (PRMS)
- **Malignant MS/Aggressive MS** refers to disease with a rapid progressive course, leading to significant disability in multiple neurologic systems in a relatively short time after disease onset.
- **Tumefactive MS** is an acute tumor-like MS variant in which some patients with demyelinating disease present with large (>2 cm) acute lesions, often associated with edema or ring enhancement.

TABLE 16.26: McDonald criteria for multiple sclerosis (MS).

Attack	***Lesion***	***Additional criteria for diagnosis MS***
2 or more	2 or more	Nonclinical evidence alone will suffice
2 or more	1 lesion	Dissemination in space of MR (or await further clinical attack implicating a different CNS site)
1 attack	2 lesions	**Dissemination in time on MR** (or await further clinical attack implicating a different CNS site)
1 attack	1 lesion	**Dissemination in space and time** (or await further clinical attack implicating a different CNS site)
0 attack **Progression from onset**		One year of disease progression (retrospective or prospective) and at least two out of three criteria ➢ Dissemination in space in the brain ➢ Dissemination in space in the spinal cord based on 2 or more T2 lesions ➢ Positive CSF

Box 16.19: Common presentations of multiple sclerosis.

- Optic neuropathy (neuritis)
- Relapsing/remitting sensory symptoms [e.g. **Lhermitte's sign** (barber chair phenomenon, is an electrical sensation that runs down the back and into the limb on neck flexion)]
- Subacute painless spinal cord lesion
- **Acute brainstem syndrome:** Sudden diplopia, and vertigo with nystagmus
- **Subacute loss of function of upper limb** (dorsal column deficit): Clumsy/useless hand or limb
- Fatigue, cognitive impairment
- Sixth cranial nerve palsy, wall-eyed bilateral internuclear ophthalmoplegia **(WEBINO)**
- Unsteadiness or ataxia. **Charcot's triad** of dysarthria, ataxia, and tremor
- Urinary symptoms—bladder hyperreflexia
- Neuropathic pain, fatigue, spasticity, depression, sexual dysfunction
- **Uhthoff's phenomenon:** Worsening of neurologic symptoms (especially vision) when the body gets overheated

Diagnosis

The diagnosis of MS is usually easily made in a young adult with relapsing and remitting symptoms referable to different areas of CNS white matter. No single diagnostic test for definitive diagnosis of MS.

Magnetic resonance imaging (Figs. 16.17A and B)

- Characteristic abnormalities are found in >95% of patients.
- Lesion appears as focal area of hyperintensity on T2-weighted.
- Typical lesions are oval up to 2 cm in diameter, and frequently orientated perpendicular to the lateral ventricular surface, corresponding to the pathologic pattern of perivenous demyelination (Dawson's fingers).
- Lesions are multifocal (periventricular, juxtacortical, infratentorial, or spinal cord).

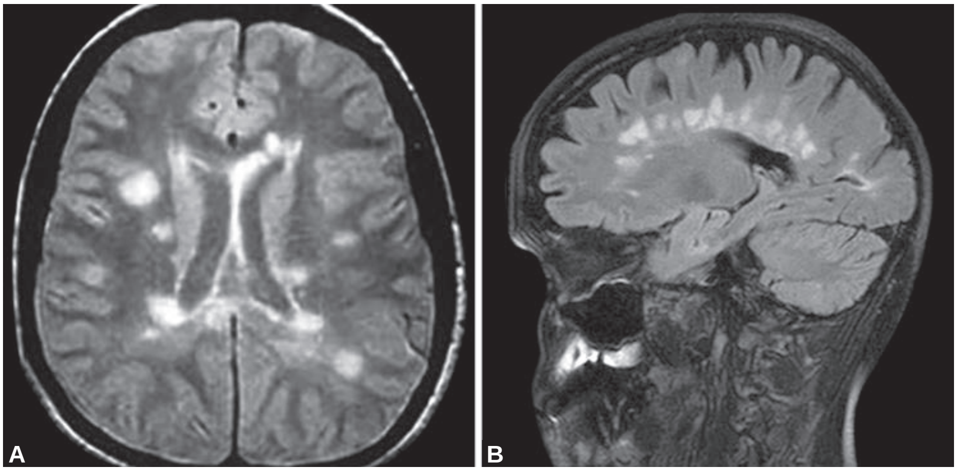
Evoked potential (EP) or evoked responses

Assesses function in afferent (visual, auditory and somatosensory) or efferent (motor) CNS pathways, abnormalities on one or more EP modalities occur in 80–90% of MS patients. However, they are less important than MRI.

Cerebrospinal fluid examination

- CSF cell count may be raised (5–60 mononuclear cells/mm)—mononuclear cell pleocytosis.
- Increased immunoglobulin G (IgG), total CSF protein, CSF IgG index.
- **Protein electrophoresis:** Oligoclonal IgG bands detected by agarose gel, but these are not specific.

McDonald criteria for MS are presented in **Table 16.26**.



FIGS. 16.17A AND B: Magnetic resonance imaging of multiple sclerosis.

Treatment of Multiple Sclerosis

- **Treatment of acute attack**
  - **Intravenous methylprednisolone** 500–1,000 mg/day for 3–5 days, followed by a course of oral prednisone beginning at a dose 60–80 mg/day and gradually tapered over 2 weeks. High-dose cyclophosphamide has been used for induction therapy to stabilize aggressive MS.
  - **Plasma exchange:** 5–7 changes are done with 40–60 mL/kg per exchange alternate days for 14 days for cases that are unresponsive to glucocorticoids.
- **Disease-modifying drugs:** For prophylaxis of RRMS and SPMS after acute stage has passed. No effective treatment for PPMS. These include interferon (IFN)-β (1a-1b), glatiramer acetate, natalizumab, mitoxantrone hydrochloride, rituximab, siponimod, fingolimod, and cladribine, oral therapies with drugs like dimethyl fumarate, diroximel fumarate, monomethyl fumarate can be considered.
- **Ocrelizumab,** a recombinant human anti-CD20 monoclonal antibody designed to optimize B-cell depletion, is the first drug to significantly reduce the risk of disability progression among patients with PPMS.
- **Symptomatic therapy**
  - **Weakness (heat-induced):** K^+ channel blockers—4-aminopyridine, 3,4-diaminopyridine
  - **Spasticity/spasm:** Physiotherapy, avoid trigger factors. Drugs like baclofen, diazepam, tizanidine, and dantrolene can be used.
  - **Pain:**
    - Anticonvulsant: Carbamazepine, phenytoin, gabapentin, pregabalin
    - Antidepressant: Amitriptyline/nortriptyline, desipramine, venlafaxine
    - Antiarrhythmic: Mexiletine
- Bladder care.

The differences between MS and neuromyelitis optica (NMO) are listed in **Table 16.27**. *It is important to differentiate as IFN is contraindicated in NMO.*

TABLE 16.27: Differences between multiple sclerosis and neuromyelitis optica (NMO).

Features	***Devic's disease (NMO)***	***Multiple sclerosis***
Age	Adults	Young adults
F:M	>3:1	<3:1
Distribution of signs and symptoms	Restricted to optic nerves and spinal cord	Any white matter
Attack severity	Usually severe	Usually mild
Brain MRI	Usually normal (rarely lesion around area postrema +)	Multiple periventricular white matter lesions
Cord MRI	Longitudinally extensive transverse myelitis (LETM) central necrotic lesions, three or more spinal cord segments involved	Multiple small peripheral lesions
CSF cells	Pleocytosis during attack	Rarely >25 cells
Oligoclonal bands	Usually absent	Usually present
Antibodies	Anti-NMO antibody (46%), anti-AQP4 (aquaporin 4) (85%) present	No antibodies
Coexisting autoimmunity	Frequent (30–40%) (Sjogren's syndrome)	Less common
Recurrence rate	Higher (90%)	Lower
Recurrence interval	Shorter	Longer

SEIZURES AND EPILEPSY

Q. PE30.8 Define epilepsy. Discuss the pathogenesis, clinical types, presentation and management of epilepsy.

Q. Describe the types, etiology, clinical features, investigations (evaluation), and management of epilepsy. Enumerate antiepileptic agents.

Q. Classify epilepsy. Describe the clinical features and treatment of grand mal (generalized tonic-clonic) epilepsy.

Q. Write a short essay/note on:

- Enumerate the causes and investigation of a seizure. Mention drugs used to treat grand mal epilepsy.
- Temporal lobe epilepsy.
- Management of complex partial seizures.
- Complications of status epilepticus (SE).
- Causes of convulsion.
- Primary epileptic disorders.
- Complications of seizures.
- Define complex partial seizure.

- **Seizure:** It is a **paroxysmal event due to abnormal, excessive, hypersynchronous discharges from** an aggregate of CNS **neurons**.
- **Epilepsy** is a chronic neurological disorder defined as the occurrence of two or more unprovoked or reflex seizures at least 24 hours apart, the occurrence of a single unprovoked or reflex seizure in an individual with an underlying condition that increases the risk of subsequent seizures (e.g., a brain tumor), or the presence of an epilepsy syndrome.
- An individual with a single seizure or recurrent seizures due to correctable or avoidable circumstances does not necessarily have epilepsy.

Classification of Seizures (Tables 16.28 and 16.29)

Q. Classify seizure/epilepsy.

- Seizures are classified as **"simple"** if there is **no impairment of consciousness** or as **"complex"** if an **alteration in consciousness** occurs. **Seizures may be either focal or generalized.**
    - *Focal seizures:* They originate within networks limited to one cerebral hemisphere across both cerebral hemispheres. They are usually **associated with structural abnormalities** of the brain.
    - *Generalized seizures:* In contrast to focal, they may result from **cellular, biochemical, or structural abnormalities** that have a more widespread distribution. However, there are clear exceptions in both cases.
- Most seizures last seconds to minutes.
- **Status epilepticus** (*discussed later*).

Focal Seizures

Focal Seizures without Dyscognitive Features

- In this type, **consciousness is fully preserved during the seizure** and the clinical manifestation is relatively simple.
- Focal seizures can cause motor, sensory, autonomic, or psychic symptoms without an obvious alteration in consciousness.
- A focal motor seizure arising from the right primary motor cortex near the area controlling hand movement will note the onset of involuntary movements of the contralateral, left hand.
- Three additional features of seizures are described here.

TABLE 16.28: New classification of seizures.

Focal seizures: It can be further described as having motor, sensory, autonomic, cognitive, or other features	
Generalized seizures	
➢ Absence (typical/atypical)	➢ Atonic
➢ Tonic-clonic (in any combination)	➢ Myoclonic
	➢ May be focal, generalized, or unclear
➢ Clonic	
➢ Tonic	
Unknown: Epileptic spasms	

TABLE 16.29: International League Against Epilepsy (ILAE) 2017 classification of seizure types.

Generalized onset seizures	
➢ Tonic-clonic	➢ Typical
➢ Clonic	➢ Atypical
➢ Tonic	➢ Myoclonic
➢ Myoclonic	➢ Eyelid myoclonia
➢ Myoclonic-tonic-clonic	
➢ Myoclonic-atonic	
➢ Atonic	
➢ Epileptic spasms	
Focal onset seizures	
Motor onset	**Nonmotor onset**
➢ Aware	➢ Aware
➢ Impaired awareness	➢ Impaired awareness
➢ Unknown awareness	➢ Unknown awareness
➢ Automatisms	➢ Autonomic
➢ Atonic	➢ Behavior arrest
➢ Clonic	➢ Cognitive
➢ Epileptic spasms	➢ Emotional
➢ Hyperkinetic	➢ Sensory
➢ Myoclonic	
➢ Tonic	
➢ Focal to bilateral tonic-clonic	➢ Focal to bilateral tonic-clonic
Unknown onset seizures	
Motor	**Nonmotor**
➢ Tonic-clonic	Behavior arrest
➢ Epileptic spasms	
Unclassified seizures	

Q. Write a short note on Jacksonian epilepsy.

Jacksonian march: Representing the **spread of seizure activity over a progressively larger region of motor cortex.** In Jacksonian seizures, march of symptoms occurs where if it is motor, clonic jerking starts at a point. For example, it may start at face, and spreads to upper limb, then to lower limb and then on to opposite side to become a generalized fit. This denotes the path of spread of the epileptic activity and is called Jacksonian spread/march.

Q. Write a short note on Todd's paralysis.

- **Todd's paralysis** or the **localized paresis:** It is a condition characterized by brief, temporary paralysis that follows a seizure. It may occur **for minutes to hours in the involved region following** the seizure.
- **Epilepsia partialis continua:** Analogous to partial SE. It is often quite refractory to medical therapy.

Other Manifestations

Changes in somatic sensation (e.g., paresthesia), vision (flashing lights or formed hallucinations), equilibrium (sensation of ailing or vertigo), and autonomic function (flushing, sweating, piloerection).

Focal Seizures with Dyscognitive Features

- Focal seizure activity may be accompanied by a transient impairment of the patient's ability to maintain normal contact with the environment.
- Patient is **unable to respond to visual or verbal commands** during the seizure and has impaired recollection or awareness of the ictal phase.
- The seizures **frequently begin with an aura** (i.e., focal seizures without dyscognitive features) that is stereotypic for the patient.
- The start of the ictal phase is often a **sudden behavioral arrest or motionless stare,** and this marks the onset of the event for which the patient will be amnesic.
- The behavioral arrest is usually accompanied by oromandibular or hand automatisms, which are involuntary, automatic behaviors that have a wide range of manifestations.
- **Automatisms** may consist of very basic behaviors such as chewing, lip smacking, swallowing or picking movements of the hands or more elaborate behaviors such as a display of emotion or running.

Complex Partial Seizures (Temporal Lobe Seizures)

Focal seizures arising from the temporal or frontal cortex may also cause alterations in hearing, olfaction or higher cortical function (psychic symptoms-like to sensation of unusual intense odors (e.g., burning rubber or kerosene) or sounds (crude or highly complex sounds) or illusions that objects are growing (metamorphopsia) smaller (micropsia) or larger (macropsia). When such symptoms precede focal seizures with dyscognitive features or secondarily generalized seizure, these seizures serve as a warning, or aura.

Generalized Seizures

- Generalized seizures **arise from both cerebral hemispheres simultaneously.**
- It may be practically defined as **bilateral clinical and electrographic events without any detectable focal onset.**
- Though they arise at some point of the brain they rapidly engage neuronal networks in both cerebral hemispheres.

Absence Seizures (Petit Mal Seizures)

- Sudden, brief lapses of **consciousness without loss of postural control.**
- **It lasts for only a few seconds and consciousness returns rapidly** and there is no postictal confusion.
- Usually accompanied by subtle, bilateral motor signs such as rapid blinking of the eyelids, chewing movements, or small amplitude, clonic movements of the hands. Absence seizures can be typical or atypical.
- Onset usually in childhood (ages 4–8 years) or early adolescence and are the main seizure type in 15–20% of children with epilepsy.
- May occur hundreds of times in a day without the knowledge of parents or the child.
- First clue may be often unexplained "daydreaming" and a decline in school performance recognized by a teacher.
- **Electroencephalography (EEG):** Generalized, symmetric, 3-Hz spike-and-wave discharge that begins and ends suddenly, superimposed on a normal EEG background which can be provoked by hyperventilation.

Generalized Tonic-Clonic Seizures (Grand Mal Seizures)

Q. Write a short essay/note on clinical features and treatment of grand mal (generalized tonic-clonic) epilepsy.

- Main type of seizure in 10% of all individuals with epilepsy.
- Usually **begins abruptly without warning.** Some may develop vague premonitory symptoms which are distinct from the stereotypic auras associated with focal seizures that generalize.
- **Initially,** there is **tonic contraction of muscles throughout the body** leading to **loud moan or ictal cry, cyanosis,** biting of the tongue, etc.
- Marked enhancement of sympathetic tone leads to increases in heart rate, blood pressure, and pupillary size.
- **After 10–20 seconds, clonic phase starts** with **superimposed relaxation** which progressively increases until the end of ictal period.
- **Postictal phase** is characterized by **unresponsiveness, muscular flaccidity, and excessive salivation, bladder or bowel incontinence**.
- Patients **gradually regain consciousness** over **minutes to hours** with accompanying postictal confusion, headache, and muscle ache.
- **EEG:** Generalized high-amplitude, polyspike discharges in tonic phases which in the clonic phase typically interrupted by slow waves to create a spike-and-wave pattern.
- **Other variants** include pure tonic and pure clonic type.

Atonic Seizures

- They are characterized by **sudden loss of postural muscle tone** lasting **1–2 seconds.**
- **Consciousness is briefly impaired,** but there is usually **no postictal confusion.**
- They may cause only a quick head drop or nodding movement, while a longer seizure will cause the patient to collapse.
- They **are rarely seen in isolation** and are usually seen in association with known epileptic syndromes.
- **EEG:** Brief, generalized spike-and-wave discharges followed immediately by diffuse slow waves that correlate with the loss of muscle tone.

Myoclonic Seizures

- Sudden, brief jerky muscle contraction that may involve one part of the body or the entire body.
- Normal, common physiologic forms of myoclonus are the sudden jerking movement observed while falling asleep and hiccups.
- Most pathologic myoclonus commonly seen in association with metabolic disorders, degenerative CNS diseases, or anoxic brain injury.
- Myoclonic seizures are the predominant feature of juvenile myoclonic epilepsy (JME).
- **EEG:** May show bilaterally synchronous spike-and-wave discharges synchronized with the myoclonus.

Epilepsy Syndromes

Epilepsy syndromes are disorders in which **epilepsy is a predominant feature,** and there is sufficient evidence to suggest a common underlying mechanism.

Juvenile Myoclonic Epilepsy

- Juvenile myoclonic epilepsy is a **generalized seizure** disorder of **unknown cause** that appears in **early adolescence** and is usually characterized by **bilateral myoclonic jerks** that may be single or repetitive.
- The myoclonic seizures are **most frequent in the morning** after awakening and can be provoked by sleep deprivation.
- Unless severe **consciousness is preserved.**
- Many patients also experience generalized tonic-clonic seizures (GTCSs), and up to one-third have absence seizures.
- The condition is otherwise benign, and although complete remission is uncommon, the seizures respond well to appropriate anticonvulsant medication.
- Lifelong treatment is necessary and **sodium valproate** is the drug of choice.

Lennox–Gastaut Syndrome

Lennox–Gastaut syndrome is seen in children between the ages of 1–8 and is characterized by the following triad:

1. **Multiple seizure types** (usually including generalized tonic-clonic, atonic, and atypical absence seizures).

2. **EEG:** Shows **slow (<3 Hz) spike and wave discharges** and a variety of other abnormalities.
3. **Impaired cognitive function** in most but not all patients.

Lennox–Gastaut syndrome is an epileptic encephalopathy **associated with CNS disease or dysfunction** from a variety of causes, including developmental abnormalities, perinatal hypoxia/ischemia, trauma, infection, and other acquired lesions.

- The multifactorial nature of this syndrome suggests that it is a nonspecific response of the brain to diffuse neural injury.
- A similar syndrome in infancy that often evolves into Lennox–Gastaut syndrome is **West syndrome,** characterized by infantile spasms, Salaam attacks, other findings of cerebral dysfunction, and abnormal EEG pattern (hypsarrhythmia).

Mesial Temporal Lobe Epilepsy Syndrome

- Mesial temporal lobe epilepsy (MTLE) is the **most common syndrome** associated with complex partial seizures and is an example of symptomatic, partial epilepsy.
- Characteristic **hippocampal sclerosis** on MRI is an essential element in the pathophysiology of MTLE for many patients.
- Recognition of this syndrome is especially important because it tends to be **refractory to treatment with anticonvulsants but responds extremely well to surgical intervention.**

Febrile Seizures

- Usually occurs between **3 months and 5 years of age** and have a peak incidence between 18 and 24 months.
- It **is GTCS** in child **during a febrile illness** in the setting of a common childhood infections.
- The seizure is likely to occur during the rising phase of the temperature curve (i.e., during the first day).
- A **simple febrile seizure** is a **single, isolated** event, brief and symmetric in appearance. **Complex febrile seizures** are characterized **by repeated seizure activity,** duration >15 minutes, or by focal features.
- Simple febrile seizures are not associated with an increase in the risk of developing epilepsy; while complex febrile seizures have a risk of 2–5%. Other risk factors include the presence of pre-existing neurologic deficits and a family history of nonfebrile seizures.

Causes of Seizures According to Age

See **Box 16.20**.

Evaluation of the Patient with a Seizure

- When a patient is seen shortly after a seizure, the first priorities are **attention to vital signs, respiratory and cardiovascular support,** and **treatment of seizures if they resume.**
- When the patient is not acutely ill, the evaluation will initially focus on whether or not there is a history of earlier seizures.

First Seizure

If this is the patient's first seizure, then the emphasis will be to **establish whether** the reported **episode was a seizure** rather than another paroxysmal event.

In case of GTCS, features supporting organicity are postictal confusion, tongue bite, history of fall or having sustained injury, etc.

- **Determine the cause of the seizure** by identifying risk factors and precipitating events. Precipitating factors such as sleep deprivation, systemic diseases, electrolyte or metabolic derangements (like hypoglycemia, hyper and hypocalcemia, hyponatremia hypomagnesemia) acute infection, drugs that lower the seizure (like penicillin, quinolones, antipsychotics, lithium, amphetamine, barbiturates, cocaine) threshold or alcohol or illicit drug use should be identified.
- **General physical examination:** Look for signs of system illnesses or infection. Careful examination of the skin may reveal signs of neurocutaneous disorders such as tuberous sclerosis or neurofibromatosis, or chronic liver or renal disease. Organomegaly may indicate a metabolic storage disease, and limb asymmetry may provide a clue to brain injury early in development.

Box 16.20: Causes of seizures according to age.

Neonates (<1 month)
- Perinatal hypoxia and ischemia
- Intracranial hemorrhage and trauma
- CNS infections
- Metabolic

Infants and children (>1 month and <12 years)
- Febrile seizures
- Genetic disorders (metabolic, degenerative, primary epilepsy syndromes)
- CNS infections

Adolescents (12–18 years)
- Trauma
- Genetic disorders
- Infection

Young adults (18–35 years)
- Trauma
- Alcohol withdrawal

Older adults (>35 years)
- Cerebrovascular disease
- Trauma (including subdural hematoma)
- Brain tumor
- Alcohol withdrawal
- Degenerative diseases

- Finally **decide whether anticonvulsant therapy is required** in addition to treatment for any underlying illness. It is usually not required in case of metabolic or electrolyte derangements and seizures due to alcohol withdrawal.
- If no metabolic or infectious causes found, then look for:
  - Focal features of seizure
  - Any focal neurological deficits
  - Any other neurological dysfunction/mental retardation
- Unusual features such as, prolonged duration of seizures (>6 hours), more than six seizures, SE, or a prolonged postictal state.
  - If present, usually antiepileptic therapy is required. Then MRI and EEG are done to find any mass lesion/stroke/degenerative lesion. Treatment of underlying cause besides antiepileptic therapy.
  - If absent, it is idiopathic epilepsy and antiepileptic therapy continued.

Recurrence of a Seizure

In the patient with prior seizures or a known history of epilepsy, the evaluation is directed toward:

- **Identification of the underlying cause and precipitating factors:** Common precipitating factors are—sleep deprivation, fever, hypoglycemia, and alcohol.
- **Determination of the adequacy of the patient's current therapy:**
  - If no precipitating factors found, measure the plasma concentration of AED.
  - If subtherapeutic concentration: Appropriate increase in drug dosage is done.
  - If therapeutic concentration is normal: Either drug increased to maximum tolerated dose or alternate therapy is started with gradually tapering the first drug.

Laboratory Studies

- **Routine investigations:** These include serum glucose, calcium, electrolytes, renal and hepatic functions.
- **Lumbar puncture:** If indicated.
- **EEG:** May help establish the diagnosis of epilepsy, classify the seizure type, and provide evidence for the existence of a particular epilepsy syndrome.
  - The presence of electrographic seizure activity (i.e., of abnormal, repetitive, rhythmic activity having an abrupt onset and termination, clearly establishes the diagnosis).
  - The EEG findings may also be helpful in the interictal period by showing certain abnormalities that are strongly supportive of an epilepsy. Such epileptiform activity consists of bursts of abnormal discharges containing spikes or sharp waves.
  - EEG is normal in 40% of epileptic patients.
- Neuroimaging studies (MRI preferred over CT).

The differences between seizures and syncope are listed in **Table 16.30**.

TABLE 16.30: Differences between seizures and syncope.

Features	*Seizures*	*Syncope*
Immediate precipitating factor	Usually none	Emotional stress, Valsalva, orthostatic hypotension, cardiac etiologies
Premonitory symptoms	None or aura (e.g., odd odor)	Tiredness, nausea, diaphoresis, tunneling of vision
Posture at onset	Variable	Usually erect
Transition to unconsciousness	Often immediate	Gradual over seconds
Duration of unconsciousness	Minutes	Seconds
Duration of tonic or clonic movements	30–60 seconds	Never >15 seconds
Facial appearance during event	Cyanosis, frothing at mouth	Pallor
Disorientation and sleepiness after event	Many minutes to hours	<5 minutes
Headache, muscle pain, tongue bite incontinence	Often, tongue bite—lateral	Rarely, tongue bite—tip

Treatment

Indications to Initiate Antiepileptic Drug Therapy

Antiepileptic drug therapy should be **started in any patient with recurrent seizures of unknown etiology** or a **known cause that cannot be reversed with in short time.** Risk factors associated with recurrent seizures are listed in **Box 16.21**.

Selection of AEDs **(Table 16.31)**: Certain AEDs like phenytoin and carbamazepine can worsen myoclonic seizure. Hence proper AED for proper seizure must be given.

Treatment Modification

- If a treatment is modified recently, one should wait for at least four half-lives of the drug before further modifying dosage.

- If one drug is unable to control seizures then another drug should be considered when either maximum dose of the first drug is reached or the patient starts showing intolerable side effects.
- Whenever a new drug is added, the first drug is continued till the second drug controls seizures. Only after achieving adequate seizure control the first drug should be gradually withdrawn.

Indications for Discontinue Therapy

- Complete medical control of seizures for 1–5 years.
- Single seizure type, either focal or generalized.
- Normal neurologic examination (including intelligence)
- Normal EEG

  In most cases, it is preferable to reduce the dose of the drug gradually over 2–3 months.

  Most recurrences occur in the first 3 months after discontinuing therapy, and patients should be advised to avoid potentially dangerous situations such as driving or swimming during this period.

Treatment of Refractory Epilepsy

- Therapy combines first-line drugs (i.e., carbamazepine, phenytoin, valproic acid and lamotrigine).
- If these drugs are unsuccessful, then the addition of a newer drug such as levetiracetam and topiramate is indicated.
- Patients with myoclonic seizures resistant to valproic acid may respond to a combination of valproic acid and ethosuximide.

Box 16.21: Risk factors associated with recurrent seizures.

- An abnormal neurologic examination
- Seizures presenting as status epilepticus
- Postictal Todd's paralysis
- Strong family history of seizures
- An abnormal EEG
- Abnormal CT or MRI

TABLE 16.31: Selection of antiepileptic drugs in seizures.

Seizure types	*First choice*	*Second choice*
Monotherapy for generalized-onset tonic-clonic seizures	Valproate, topiramate	Zonisamide, levetiracetam, lamotrigine phenytoin, carbamazepine
Absence seizure	Ethosuximide, valproate	Zonisamide, levetiracetam, topiramate, felbamate, clonazepam
Monotherapy for partial seizures	Carbamazepine, oxcarbazepine, phenytoin, topiramate	Lamotrigine, gabapentin, levetiracetam
Myoclonic	Valproate, levetiracetam, clonazepam	Zonisamide, topiramate
Status epilepticus	Diazepam, lorazepam	Phenytoin IV, fosphenytoin IV
Febrile convulsions	Diazepam rectal 0.5 mg/kg	
Infantile spasms	Corticotropin, corticosteroids, zonisamide	Clonazepam, nitrazepam, vigabatrin, phenobarbital

Surgical Treatment of Refractory Epilepsy

- About 20–30% of patients with epilepsy are resistant to medical therapy. **Ketogenic diet**—has been advised to decrease seizure recurrence. Low carbohydrate, adequate protein, high fat has been advised.
- **Anteromedial temporal lobe** (temporal lobectomy) or a **more limited removal of the underlying hippocampus** and **amygdala** (amygdalohippocampectomy).
- Focal seizures arising from extratemporal regions may be abolished by a focal neocortical resection with precise removal of an identified lesion (lesionectomy).
- **Others:** Hemispherectomy, corpus callosotomy, etc.
- **Vagus nerve stimulation (VNS)** may be used—some of these cases, although the benefit for most patients seem to very limited.

Antiepileptic drugs for chronic use have been shown in Tables 16.32 and 16.33.

TABLE 16.32: Antiepileptic drugs for chronic use.

Type of drug		*Examples*
Na^+ channel blockers		Phenytoin, carbamazepine, oxcarbazepine, primidone, valproic acid, lamotrigine, topiramate, zonisamide, phenobarbital, gabapentin, felbamate
Ca^{2+} channel blockers		Ethosuximide, phenobarbital, zonisamide
Drugs that potentiate GABA	Increase opening time of channel	Phenobarbital
	Increase frequency of openings of channel	Diazepam, lorazepam, clonazepam
	Increase GABA in synapse	Valproic acid
	Increase GABA metabolism	Gabapentin
	Increase GABA release	Gabapentin
	Block GABA transaminase	Vigabatrin
	Block GABA transporter (GAT-1)	Valproic acid, tiagabine
	Facilitate GAD (glutamic acid decarboxylase) Increase GABA synthesis	Valproic acid
	Synaptic vesicle protein 2A binding	Levetiracetam (inhibits presynaptic calcium channels)
	AMPA agonist	Perampanel

TABLE 16.33: Antiepileptic drugs and their mechanism of action, adverse reactions, and uses.

Drug and mechanism of action	***Adverse reactions***	***Uses***
Phenytoin: Oldest nonsedative antiepileptic drug. It alters Na^+, Ca^{2+}, and K^+ conductances	Ataxia and nystagmus, cognitive impairment, hirsutism, gingival hyperplasia, coarsening of facial features, dose-dependent zero order kinetics, exacerbates absence seizures, "Fetal hydantoin syndrome"	Partial seizure, generalized (including tonic-clonic) seizures. Contraindicated in absence seizures **Nonseizure indications** include trigeminal neuralgia, manic-depressive disorders
Carbamazepine: Tricyclic, antidepressant (bipolar) Mechanism of action, similar to phenytoin. Inhibits high-frequency repetitive firing (Na^{++})	Autoinduction of metabolism, nausea and visual disturbances, granulocyte suppression, aplastic anemia, exacerbates absence seizures	Partial seizure (including tonic-clonic) seizures. **Contraindicated in absence seizures.** **Nonseizure indications** include trigeminal neuralgia, manic-depressive disorders
Oxcarbazepine: Related to carbamazepine. With improved toxicity profile. Less potent than carbamazepine. Active metabolite	Hyponatremia, less hypersensitivity and induction of hepatic enzymes than with carbamazepine	
Phenobarbital: It is the oldest antiepileptic drug. Although considered one of the safest drugs, it has sedative effects Prolongs opening of Cl^- channels. Blocks excitatory GLU (AMPA) responses. Blocks Ca^{2+} currents (L, N)	Sedation, cognitive impairment, behavioral changes, induction of liver enzymes, may worsen absence and atonic seizures	Useful for partial, generalized tonic-clonic seizures, and febrile seizures
Primidone: Metabolized to phenobarbital and phenylethylmalonamide (PEMA), both active metabolites	Same as phenobarbital. Sedation occurs early. Gastrointestinal disturbances	Effective against partial and generalized tonic-clonic seizures
Valproate: Mechanism of action, similar to phenytoin. Increases levels of GABA in brain. May facilitate glutamic acid decarboxylase (GAD). Inhibits GAT-1	Elevated liver enzymes, nausea and vomiting, abdominal pain, heartburn, tremor, hair loss, syncretic, hepatotoxicity, teratogen (spina bifida)	A broad-spectrum antiseizure drug effective for partial and generalized seizures, including myoclonic and absence seizures. Nonseizure indications include migraine (prophylaxis), bipolar disorder
Ethosuximide: Reducing low-threshold Ca^{2+} channel current (T-type channel) in thalamus	Gastric distress, including pain, nausea and vomiting, lethargy and fatigue, headache, hiccups, euphoria, skin rashes	Drug of choice for absence seizures
Clonazepam: One of the most potent antiepileptic agents known	Sedation is prominent. Ataxia, behavior disorders	Long-acting drug with efficacy for absence seizures. Also effective in some cases of myoclonic seizures. Has been tried in infantile spasms
Lamotrigine: Suppresses sustained rapid firing of neurons and produces a voltage and use-dependent inactivation of sodium channels, thus its efficacy in partial seizures	Dizziness, headache, diplopia, nausea, somnolence, rash	Presently use as add-on therapy with valproic acid. Also effective in generalized and myoclonic seizures in childhood and absence seizures preferred in elderly
Topiramate: Potentiates inhibitory effects of GABA (acting at a site different from BDZs and BARBs)	Somnolence, fatigue, dizziness, cognitive slowing, paresthesia, nervousness, confusion, urolithiasis	Myoclonic seizures, migraine
Zonisamide: Sulfonamide derivative	Drowsiness, cognitive impairment, high incidence of renal stones	Effective against partial and generalized tonic-clonic seizures
Felbamate	Aplastic anemia, severe hepatitis	Third-line drug used only for refractory partial seizure cases
Vigabatrin (gamma-vinyl GABA): Irreversible inhibitor of GABA-aminotransferase	Drowsiness, dizziness, weight gain, agitation, confusion, psychosis	Use for infantile spasms, partial seizures, and contraindicated if preexisting mental illness is present
Tiagabine: GABA uptake inhibitor GAT-1	Dizziness, nervousness, tremor, difficulty concentrating, depression, asthenia, emotional liability, psychosis, skin rash	Effective against partial and generalized tonic-clonic seizures
Gabapentin: Analog of GABA that does not act on GABA receptors. Low potency	Somnolence, dizziness, ataxia, headache, tremor	Used as an adjunct in partial and generalized tonic-clonic seizures, neuropathy
Levetiracetam	Somnolence, incoordination, irritability, mood swings, psychosis	Effective for GTCS, JME. Preferred in elderly

Newer AEDs (third-generation AEDs): Carisbamate, eslicarbazepine, brivaracetam, carabersat, ganaxolone, huperzine, lacosamide, losigaine, remacemide, retigabine, rufinamide, safinamide, perampanel.

Drug-resistant epilepsy/intractable epilepsy may be defined as failure of adequate trials of two tolerated and appropriately chosen and used antiseizure drug schedules to achieve sustained seizure freedom. Nonmedical management can be tried.

- Surgical treatments—lobar and multilobar resections, hemispherectomy, corpus callosotomy, multiple subpial transections
- Vagus nerve stimulation
- Responsive cortical stimulation
- Subcortical deep brain stimulation
- Transcranial magnetic stimulation
- Trigeminal nerve stimulation
- Ketogenic diet (high-fat, low protein) diet has demonstrated efficacy in children.

Status Epilepticus

Q. PE30.9 **Define status epilepticus. Discuss the clinical presentation and management.**

Q. **Write a short essay/note on definition, complications of SE, and its emergency management.**

Status epilepticus refers to **continuous seizures or repetitive, discrete seizures with impaired consciousness** in the interictal period.

Status epilepticus is an epileptic seizure of >5 minutes or more than one seizure within a 5-minute period without the patient returning to normal between them. Previous definitions used a 30-minute time limit.

Subtypes

- **Generalized convulsive status epilepticus (GCSE)** (e.g., persistent, generalized electrographic seizures, coma and tonic-clonic movements).
- **Nonconvulsive status epilepticus** (e.g., persistent absence seizures or focal seizures, confusion or partially impaired consciousness, and minimal motor abnormalities).

Etiology of Status Epilepticus

See **Box 16.22**.

Box 16.22: Etiology of status epilepticus.

- Stroke, including hemorrhagic
- Low AED levels
- Alcohol withdrawal
- Anoxic brain injury
- Metabolic disturbances
- Remote brain injury/congenital malformations
- Infections
- Brain neoplasms
- Idiopathic

Clinical Features

- Self-perpetuating, GTCS or
- Series of GTCSs
- Without return to consciousness in between seizures.

Phases

- **Initial compensatory phase:** Sympathetic overdrive, increased CO, increased BP.
- **Decompensation** → homeostatic failure
  - Reduced → CO/sugar/lactate/O_2 levels leading to:
    - Cardiorespiratory collapse
    - Electrolyte imbalance
    - Rhabdomyolysis and delayed tubular necrosis
    - Hyperthermia
    - Multiorgan failure (MOF)
    - Raised ICP and cerebral edema.

Complications

These include aspiration, hypotension, cardiac arrhythmias and renal or hepatic failure.

Diagnosis

- **Diagnosis of nonconvulsive SE in critically ill patients.**
- Correlate with poorer outcome.
- EEG patterns are difficult to interpret (equivocal patterns)—criteria are **not** validated.
- A trial of rapidly acting IV AED is used to observe improvement in both clinical → EEG by several hours.

Management of Status Epilepticus (Box 16.23)

- Convulsive/nonconvulsive.
- Other available modalities:
  - Brain imaging (perfusion/metabolic imaging)
  - Intracranial monitoring with intracortical EEG
  - Brain tissue O_2 monitoring
  - Cerebral microdialysis.

Pregnancy and Epilepsy

- In approximately 50% epileptic women, the frequency of epilepsy remains the same. In about 30% it increases and in about 20% it decreases in frequency.
- Uncontrolled seizure in mother causes harm to both mother and fetus more than the teratogenic effects of AEDs. Hence, pregnant women should be maintained on effective drug therapy.
- Due to the numerous side effects phenytoin is not used in pregnancy. Neural tube defects are associated with valproic acid and carbamazepine.

Box 16.23: Management of status epilepticus (SE).

First 5 minutes

- Check emergency ABCs
- Give O_2
- Obtain IV access
- Begin ECG monitoring
- Check finger stick glucose
- Draw blood for serum electrolytes. RFT, magnesium, calcium, phosphate, CBC, LFTs, AED levels, ABG, troponin
- Toxicology screen (urine and blood)

6–10 minutes

- Thiamine 100 mg IV; 50 mL of D50 IV unless adequate glucose known
- Lorazepam 4 mg IV over 2 minutes; if still seizing, repeat × 1 in 5 minutes
- If no rapid IV access give diazepam 20 mg PR or midazolam 10 mg intranasally, buccally or IM

10–20 minutes

- If seizures persist, begin fosphenytoin 20 mg/kg IV at 150 mg/min, with blood pressure and ECG monitoring

  Or
- Phenytoin 15–20 mg/kg at 30–50 mg/min

  Reasonable to bypass this step, or perform subsequent step simultaneous with fosphenytoin loading

10–60 minutes: One (or more) of the following four options (intubation usually necessary except for valproate):

1. Continuous IV midazolam. Load: 0.2 mg/kg; repeat 0.2–0.4 mg/kg boluses every 5 minutes until seizures stop, up to a maximum total loading dose of 2 mg/kg. Initial rate: 0.1 mg/kg/h. Continuous IV dose range: 0.05–2.9 mg/kg/h

   Or
2. Continuous IV propofol. Load: 1 mg/kg; repeat 1–2 mg/kg boluses every 3–5 minutes until seizures stop, up to maximum total loading dose of 10 mg/kg. Initial continuous IV rate: 2 mg/kg/h. Continuous IV dose range: 1–15 mg/kg/h. Avoid >48 hours of >5 mg/kg/h (increased risk of propofol infusion syndrome)

   Or
3. IV valproate: 40 mg/kg over ~10 minutes. If still seizing, additional 20 mg/kg over ~5 minutes

   Or
4. IV phenobarbital: 20 mg/kg IV at 50–100 mg/min

60 minutes

Continuous IV pentobarbital. Load: 5 mg/kg at up to 50 mg/min; repeat 5 mg/kg boluses until seizures stop. Initial continuous IV rate: 1 mg/kg/h. Continuous IV-dose range: 0.5–10 mg/kg/h; traditionally titrated to suppression-burst on EEG

Perform neuroimaging when convulsive activity is controlled

- Begin continuous EEG, if patient does not awaken rapidly or if continuous IV Rx is used
- Treat metabolic abnormalities and hypothermia
- Lumbar puncture and antibiotics can be considered if infection is suspected

SE not controlled even with anesthetic agents is called **super refractory SE**, for which IVIg/pulse steroid can be tried as last resort

- Carbamazepine is considered relatively safe in pregnancy, because of its low teratogenic potential. **Levetiracetam is safest drug.**
- If mother is on phenobarbital, she should be given oral vitamin K (20 mg daily) in the last 2 weeks of pregnancy, and the infant should be given an intramuscular injection of vitamin K (1 mg) at birth. This is because phenobarbital may cause a transient and reversible deficiency of vitamin K-dependent clotting factors in up to 50% of newborn infants.

NEUROINFECTIONS

Q. Classify meningitis. List the causes of meningitis.

Classifications of Meningitis (Box 16.24)

Box 16.24: Classifications of meningitis.

Infective

1. **Bacterial meningitis**
   - Common organisms: *Streptococcus pneumoniae, Neisseria meningitidis, Haemophilus influenzae*
   - Uncommon organisms: *Staphylococcus aureus, Staphylococcus epidermidis,* Group B streptococci, *Escherichia coli, Klebsiella, Proteus spp., Listeria monocytogenes*
   - Rare organisms: *Salmonella, Shigella, Clostridium perfringens, Neisseria gonorrhoeae*
2. **Tuberculous meningitis (TBM):** *Mycobacterium tuberculosis*
3. **Viral meningitis (aseptic meningitis)**
   - Enteroviruses (coxsackie virus, poliovirus)
   - Mumps virus
   - Arboviruses
   - Human immunodeficiency virus (HIV)
   - Herpes simplex-2
4. **Spirochetal:** Leptospirosis, Lyme disease, syphilis
5. **Rickettsial:** Typhus fever
6. **Protozoal:** Cysticerci, amoeba, Naegleria
7. **Fungal:** *Cryptococcus neoformans, Candida, Histoplasma, Blastomyces, Coccidioides, Sporothrix*

Noninfective (sterile)

1. **Malignant disease**
   - Breast cancer
   - Bronchial cancer
   - Leukemia (leukemic meningitis)
   - Lymphoma
2. **Subarachnoid** hemorrhage (SAH) (causes meningismus)
3. **Inflammatory disease (may be recurrent)**
   - Sarcoidosis
   - Systemic lupus erythematosus, rheumatoid arthritis
   - Behçet's disease
   - Vasculitis

Cerebrospinal Fluid

- Cerebrospinal fluid is formed within the ventricles and circulates in the subarachnoid space (between arachnoid and pia matter) and in the ventricles. The total volume of CSF in adults ranges from 90 to 150 mL. It is a medium for transfer of substances from brain and spinal cord into the blood.
- **Importance of CSF examination:** Analysis of the CSF is of diagnostic importance in conditions like meningitis or primary/ metastatic tumor of CNS with CSF involvement.
- **Collection of CSF:** CSF is usually obtained by lumbar puncture using a lumbar puncture needle under strict aseptic conditions.

Lumbar Puncture

Q. Write a short essay on the procedure indications, contraindications, and complications of lumbar puncture.

- Lumbar puncture is the technique **(Fig. 16.18)** done to obtain CSF sample and also provides an indirect measure of ICP.

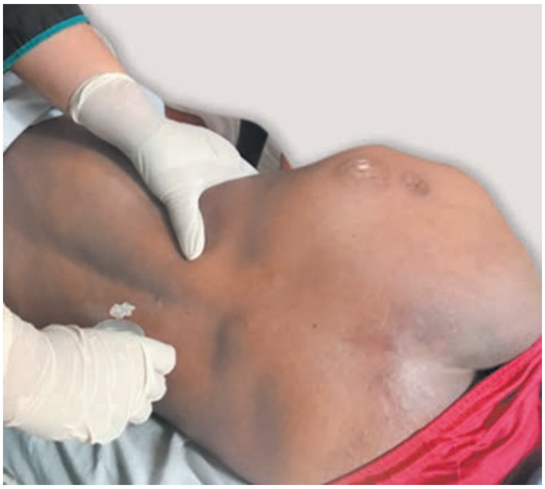


FIG. 16.18: Procedure of lumbar puncture (LP).

- After local anesthetic injection, a lumbar puncture needle is inserted in the midline between lumbar spinous processes usually between L3 and L4 (3rd **lumbar space)** through the dura and into the spinal canal. In children, it is collected from the 4th lumbar space.
- Intracranial pressure can be assessed (if patients are lying on their side) and CSF obtained for analysis.
- CSF pressure is important in the diagnosis and monitoring of idiopathic intracranial hypertension.

Indications and contraindication for lumbar puncture (Box 16.25).

Complications of Lumbar Puncture

- Most common complication is **postspinal headache.** Herniation of cerebellum through the foramen magnum due to raised ICP.
- Hematoma, either extradural or subdural.
- Introduction of infection by the lumbar puncture needle through the infected skin or subcutaneous tissue.

Normal CSF findings are presented in **Table 16.34**.

- CSF osmolality and sodium level are same as that of serum
- Constituents that are in higher concentration in CSF than in blood include magnesium, chloride, H^+ concentration and lactate.

TABLE 16.34: Normal CSF findings.

Constituent	*Normal value*
CSF volume	150 mL
CSF pressure	90–180 mm of water
Cell count	<5 cells, all lymphocytes, no neutrophils
CSF proteins	15–45
CSF sugar	60–80% of blood glucose

Q. Write a short note on causes of elevated CSF proteins.

Causes of low sugar in CSF: Pyogenic, tuberculous, fungal and carcinomatous meningitis.

Causes of elevated protein in CSF are presented in **Box 16.26**.

Box 16.25: Indications and contraindications for lumbar puncture.

Indications for lumbar puncture

- **Diagnostic indications**
  - **Infection:**
    - **Meningeal infection:** Bacterial (pyogenic, tuberculosis, syphilitic (to differentiate general paresis of insane, tabes dorsalis, and meningeal syphilis), viral, fungal
    - **Encephalitis**
  - **Subarachnoid hemorrhage**
  - **Primary or metastatic malignancy** (e.g., acute leukemia, lymphoma)
  - **Demyelinating diseases:** Multiple sclerosis and subacute sclerosing panencephalitis (SSPE)
  - **Guillain–Barré syndrome**
  - **Spinal canal blockage** leading to elevated intracranial tension (spinal cord tumors)
  - **Injecting the radiopaque dye for myelography**
- **Therapeutic indications**
  - Spinal anesthesia, epidural analgesia
  - **Intrathecal injection of chemotherapeutic drugs** for CNS prophylaxis/relapse of ALL, lymphomas
  - Therapeutic CSF drainage in cases of normal pressure hydrocephalus

Contraindications for lumbar puncture

- Raised intracranial pressure, coagulopathy
- Local infective lesion
- Bony deformities at site of puncture

Box 16.26: Causes of elevated CSF proteins.

- Meningitis
- Brain abscess
- Brain or spinal cord tumors
- Multiple sclerosis
- Guillain–Barré syndrome
- Syphilis
- Hemorrhage
- Froin's syndrome

Q. Write a short note on xanthochromia in CSF analysis.

Xanthochromia is the yellowish appearance of CSF.

Causes: Xanthochromia is always pathological and conditions associated with it are:

- **Old SAH:** The yellow appearance is due to RBCs which may leak into the CSF during the hemorrhage. RBCs are breakdown and liberate hemoglobin which is converted into yellow bilirubin.
- Other causes are high protein in the CSF, jaundice, and Froin's syndrome.

Meningitis and Encephalitis

Q. MI5.1 Describe the etiopathogenesis, clinical course and discuss the laboratory diagnosis of meningitis.

Q. What are the causes of meningitis? Discuss the clinical features, investigations, diagnosis, complications, and management of acute pyogenic (bacterial/meningococcal) meningitis.

Acute Bacterial (Pyogenic/Purulent) Meningitis

Q. Write a short essay/note on the common organisms causing pyogenic meningitis.

Relative frequency of various bacterial species causing meningitis varies with age.

- **Neonatal period:** Major causative agents include gram-negative bacilli (principally *Escherichia coli*), *Listeria monocytogenes,* and group B streptococci.
- **Infants and children:** Major causes in children beyond 1 month of age are *Haemophilus influenzae* and *Neisseria meningitidis.*
- **Adolescents and in young adults:** *Meningococcus (N. meningitidis)* is the most common pathogen.
- **Extremes of life:** *Streptococcus pneumoniae* and *L. monocytogenes.*

Causes of community acquired bacterial meningitis: Important causes are:

- *S. pneumoniae* (50%)*:* Most common.
- *N. meningitidis* (25%): It is the only major cause of epidemics of bacterial meningitis.
- Group B *streptococci* (15%)
- *L. monocytogenes* (10%)
- *H. influenzae* (10%)

Predisposing conditions

- ***For Pneumococci:*** Other *Pneumococcal* infections (pneumonia, sinusitis, otitis media), splenectomy, hypogammaglobulinemia, complement deficiency.
- ***For Neisseria meningitidis:*** Complement deficiency (including properdin), B-serotype (not protected by vaccine is responsible for one-third of cases). Usually associated with petechial or purpuric skin lesions.
- ***Listeria monocytogenes:*** Important cause in neonates (<1 month), pregnant women, >60 years and immunocompromised persons.

Box 16.27: Classical signs of meningitis.

- Cervical rigidity/neck stiffness
- **Kernig's sign:** Knee pain with hip flexion
- **Brudzinski's sign:** Knee/hip flexion when the neck is flexed

Clinical manifestations

Q. Write a short essay/note on physical signs of meningitis.

- **Classic triad:** (1) Fever, (2) headache, and (3) nuchal rigidity.
- **Consciousness:** Vary from lethargy to coma (>75%).
- Nausea, vomiting and photophobia are common.
- **Seizure/convulsions** (especially in children) may be initial presentation or present during course (20–40%).
  - *Focal:* Due to arterial ischemia, infarction, cortical venous thrombosis or focal edema.
  - *Generalized or status:* Due to hyponatremia, cerebral anoxia or toxic effects of antimicrobial drugs.
- **Classic signs of meningitis (Box 16.27).**
- **Occasionally cranial nerve palsies,** with focal neurologic deficits such as visual field defects, dysphasia, and hemiparesis may occur.
- **In meningococcus: Rash** begin as diffuse erythematous maculopapular that become petechial, found on trunk, lower limbs, mucous membrane, conjunctiva and rarely on palm and sole.
- **Raised ICP:** One of the complications of bacterial meningitis and CSF pressure may be raised to 180–400 mm H_2O. Disastrous complication of ICP is cerebral herniation.
  - *Other signs:* Reduced level of consciousness, papilledema, dilated poorly reactive pupil, VIth cranial palsy, decerebrate posture, Cushing reflex (bradycardia, hypertension, and irregular respiration).

Complications of bacterial meningitis

See **Box 16.28**.

Box 16.28: Complications of bacterial meningitis.

- Obstructive hydrocephalus
- Thrombophlebitis of leptomeningeal veins may lead to venous thrombosis, cerebral infarction, focal infection of the underlying brain parenchyma
- Chronic adhesive arachnoiditis
- Cerebral abscess
- Subdural empyema
- Focal neurologic deficits (e.g., cranial nerve palsy, hemiparesis)
- Sensorineural hearing loss
- Vasculitis of cranial vessel
- Epilepsy
- Waterhouse–Friderichsen syndrome: It results from meningitis-associated septicemia with hemorrhagic infarction of the adrenal glands and cutaneous petechiae. It occurs most often with meningococcal and pneumococcal meningitis

Diagnosis

- **By examination of the CSF:** It is usually obtained by lumbar puncture. Lumbar puncture should be postponed if there is papilledema and or focal neurologic findings suggestive of an intracranial mass lesion. It can be done only after ruling out the same by CT or MRI.
- **Blood culture:** If meningitis seems likely, blood should be sent for culture and sensitivity and empirical antimicrobial therapy should be started while the neuroimaging study is being carried out.

CSF findings in bacterial meningitis (refer ***Table 16.38****)*

Q. Write a short essay/note on CSF findings pyogenic/bacterial meningitis.

Q. Write a short essay/note on treatment of pyogenic meningitis.

Treatment

Antibiotics used in empirical therapy of bacterial meningitis and focal CNS infections.

A. *Empirical therapy (Table 16.35)*

Streptococcus pneumoniae and *Neisseria meningitidis* are common organisms. Due to emergence of penicillin and cephalosporin resistant of *S. pneumoniae* a combination therapy of 3rd or 4th generation cephalosporin (ceftriaxone, cefotaxime, cefepime) and vancomycin, plus acyclovir (HSV is a differential diagnosis) and doxycycline (tick infection) is given as empirical therapy.

TABLE 16.35: Empirical therapy for bacterial meningitis depending on the age group/predisposing factors.

Age group/predisposing factors	***Drug used***
Infants <1 month	Ampicillin + cefotaxime
Infants 1–3 months	Ampicillin + cefotaxime/ceftriaxone
Infants >3 months and adults <55 years	Cefotaxime/ceftriaxone/cefepime + vancomycin
Adults >55 years or adult with alcohol or debilitating conditions	Ampicillin + cefotaxime/ ceftriaxone/ cefepime + vancomycin
Hospital acquired, post-traumatic, postneurosurgery, neutropenic patients or impaired cell-mediated immunity	Ampicillin + ceftazidime/ meropenem + vancomycin

B. *Specific antimicrobial therapy*

- ***Neisseria meningitidis***
  - *Penicillin sensitive:* Penicillin G—250,000–300,000 U/kg/day in divided doses, Ampicillin (3 g IV TID/QID).
  - *Penicillin resistant:* Ceftriaxone 2 g IV BID/Cefotaxime 2 g IV BID.
  - 7 days IV dose are adequate.
  - All close contacts should be given chemoprophylaxis with rifampicin for 2 days or azithromycin (500 mg once) or one IM ceftriaxone (250 mg).
- ***Streptococcus pneumoniae***
  - Should be tested for penicillin and cephalosporin sensitivity
  - *Penicillin sensitive:* Penicillin G
  - *Penicillin-intermediate:* Ceftriaxone/cefotaxime/cefepime
  - *Penicillin-resistant:* Ceftriaxone/cefotaxime/cefepime + vancomycin
  - 2 weeks IV is adequate.
  - Lumbar puncture is to be repeated 24–36 hours after initiation to see the response
  - Intraventricular vancomycin may be more effective than IV or intrathecal.
- **Gram-negative bacilli (except *Pseudomonas*):** Ceftriaxone/cefotaxime for 3 weeks
- ***Pseudomonas aeruginosa:*** Ceftazidime/cefepime/meropenem
- ***Staphylococci spp.:***
  - *Methicillin sensitive:* Nafcillin
  - *Methicillin resistant:* Vancomycin (1 g IV TID) (IV or intraventricular)
- ***Listeria monocytogenes:*** Ampicillin for 3 weeks. Gentamicin may be added in critical ill cases. Trimethoprim and sulfamethoxazole are alternative
- ***H. influenzae***-intermediate: Ceftriaxone/cefotaxime/cefepime
- ***Streptococcus agalactiae:*** Penicillin G/ampicillin
- ***Bacteroides fragilis:*** Metronidazole
- ***Fusobacterium spp.:*** Metronidazole

C. *Adjunctive therapy*

- **Dexamethasone** inhibits synthesis of IL-1β and TNF-α, decrease CSF out flow resistance and stabilize blood brain barrier (BBB).
- It is to be given 20 minutes before antimicrobial therapy. It is less effective if given 6 hours after antibiotic therapy.

D. *Treatment of raised ICP*

- Elevation of head end of the bed to 30–45°, hyperventilation, and administration of mannitol.
- Duration of therapy: 7 days for *N. meningitides,* 7–10 days for *H. influenzae,* 10–14 days for *S. pneumoniae* and 3 weeks for gram-negative bacilli.

Tubercular Meningitis

Q. Describe the pathology, clinical features, investigation, complications, and treatment/management of tuberculous meningitis.

In India, tubercular meningitis (TBM) remains the most common form of meningitis.

Risk factors

- Previous history of exposure to tuberculosis or illness.
- Immunocompromised state of acquired immunodeficiency syndrome (AIDS)
- Young children.

Pathology

- Main neuropathologic finding is **basal meningeal exudates** containing mainly mononuclear cells.
- **Tubercles may** be seen on the meninges and on the surfaces of the brain.
- The **ventricles may be dilated** as a result of hydrocephalus, and the ependymal surface may be covered by **exudates.**
- **Hydrocephalus** is common in children and most develop symptoms in 2–3 weeks.
  - *Communicating type:* Common, due to blockage of basal cistern by exudates in acute phase or adhesive leptomeningitis in chronic phase.
  - *Obstructive type:* Less common, due to narrowing or occlusion of aqueduct by ependymal inflammation, tuberculomas, or obstruction of outlet of IVth ventricle.
- Arteritis can cause cerebral infarction, and basal inflammation; and fibrosis can compress cranial nerves.

Clinical features

- **Onset:** Usually subacute/chronic. Acute: children—50%, adult—14%.
- **Past history of TB:** Children—50%, adult—10%.
- **Prodromal symptoms:** Two to three weeks, vague ill health, apathy, irritability, anorexia, changes in behavior.
- **Features of meningitis:** Headache, vomiting, fever and focal neurological deficit.
- **Features of raised ICP:**
  - *Convulsions* (focal/generalized—20–30%).
  - *Cranial nerve palsy:* 20–30% (VIth cranial nerve).
  - *Loss of vision:* Partial/complete. Due to opticochiasmatic exudate, and arteritis.
- **Other presentation:** Hemiplegia, facial nerve palsy, optic atrophy, abnormal movement, oculomotor palsy, choroid tubercle, etc.
- **In untreated cases:** Consciousness deteriorates, pupillary abnormality, pyramidal signs due to hydrocephalus and tentorial herniation.

Complications of tubercular meningitis

See **Box 16.29.**

Box 16.29: Complications of tubercular meningitis.

- Raised intracranial pressure (ICP), cerebral edema
- Basal meningitis with cranial nerve palsy—II, III, IV, VI, and VII
- Focal neurologic deficit and seizure
- Hydrocephalus
- Tuberculoma
- Optochiasmatic pachymeningitis: Visual loss
- **Endocrine abnormality:** Growth hormone and gonadotropin
- **Hypothalamic disorder:** Loss of control of blood pressure (BP) and temperature, delayed or precocious sexual development
- Diabetes insipidus, syndrome of inappropriate ADH secretion (SIADH)

Investigations

Q. Write a short essay/note on laboratory diagnosis and CSF findings in tuberculous meningitis.

1. **CSF study**
   - *Cytological study*
     - **Leukocyte count:** 100–500 cells/μL, rarely >1,000/cells/μL.
     - **Cell type: Lymphocytes** predominant, polymorphonuclear cells in acute stage. Hemorrhagic due to fibrinoid necrosis of vessels. No malignant cells seen.
   - *Biochemical study*
     - **Protein:** Usually 100–200 mg/100 mL. In spinal block >1 g/100 mL and xanthochromic.
     - **On standing a pellicle/cobweb formed** indicating fibrinogen—high suggestion of TBM.
     - **Glucose:** Reduced to 20–50 mg/100 mL. In most cases <40% of corresponding blood sugar, but unlike pyogenic never undetectable.
     - **Chloride:** Low value 450–600 mg/100 mL and is nonspecific indicating hypochloremia. It may be seen in bacterial, viral meningitis also.
     - **Adenosine deaminase** (ADA) produced by T lymphocytes elevated in CSF (60–100%).
   - *Microbiological study*
     - Negative with Gram stain, Indian ink stain and culture is sterile.
     - Acid-fast bacilli (AFB): AFB in smear and culture-confirmatory but number of bacteria should be >104/ml. Stained by Ziehl–Neelsen and auramine (4–40% positive).

- **Centrifuged CSF:** The thick smear from pellicle and repeated culture enhance detection.
- **CSF culture:** In Lowenstein–Jensen media in 4–8 weeks. It may be enhanced by liquid media like Septi-Chek AFB system or Middlebrook 7H9. Isolation is better from cisternal/ventricular CSF.

2. **Radiological investigations**
   - *Chest X-ray*: It may reveal miliary mottling in the lung.
   - *CT scan*:
     - Thickening of meninges in basal cistern (60%)
     - Hydrocephalus in 50–80% depending on duration
     - Cerebral infarct (28%) in MCA, edema (periventricular), tuberculoma (10%).
3. **Immunological methods**
   - **Antibody detection:** CSF shows antibodies against various antigens that are sensitive and are detected by ELISA and RIA.
   - **Antigen detection:** More specific. Antigen is detected by Latex agglutination, ELISA, etc.
   - **Molecular methods:** Amplification of specific DNA sequence by PCR used for rapid diagnosis. PCR is confirmatory and not affected by other organisms.

Management
- Antituberculous treatment (ATT) for one and a half year in uncomplicated cases is usually sufficient.
- **Steroids:** It is recommended to give steroids during initial 6 weeks to decrease the possibility of adhesion formation. Steroids prevent complications. There is no definite duration for which treatment might be continued, but should be judged on the basis of neuroimaging findings.
- **Surgical intervention:** If hydrocephalus, tuberculoma, or abscess develops. Tubercular abscess needs drainage.

Viral Meningitis/Aseptic Meningitis

- Viral infections of the meninges (meningitis) or brain parenchyma (encephalitis) often present as acute confusional states.
- Children and young adults are frequently affected.

Etiology

Common viruses include:
- **Enteroviruses** (most common, i.e., coxsackie viruses, echoviruses, and human enteroviruses): At least **two-thirds** of the cases of CSF culture-negative aseptic meningitis are due to enteroviruses.
- **Herpes simplex virus-2 (HSV-2) meningitis:** It may occur during the initial episode of genital herpes. Most cases of benign recurrent lymphocytic meningitis (previously called as Mollaret's meningitis) appear to be due to HSV.
- **Arthropod-borne viruses:** These are transmitted through infected insect vectors.
- **Human immunodeficiency virus (HIV): Aseptic meningitis** is a common manifestation of primary exposure to **HIV. Cranial nerve palsies,** most commonly involving cranial nerves V, VII, and VIII are more common in HIV meningitis than in other viral infections.
- **Mumps** can also cause meningitis.

Clinical Manifestations

Fever, headache, and meningeal irritation. Other features include malaise, myalgia, anorexia, nausea and vomiting, abdominal pain, and/or diarrhea.

Laboratory Diagnosis

Q. Write short answer on CSF changes in viral meningitis.

- **CSF examination:**
  - Reveals lymphocytosis, mildly elevated protein and normal glucose.
  - As a rule, a **lymphocytic pleocytosis with a low glucose level** (<25 mg/dL) should **suggest** the presence of **fungal, listerial or tuberculous meningitis** or of **noninfectious disorders** (e.g., neoplastic meningitis)
- **Polymerase chain reaction (PCR):** Amplification of viral-specific DNA or RNA from CSF by PCR important method for the diagnosis of CNS viral infection.

Treatment
- **Symptomatic** and hospitalization is not required.
- **Oral or IV acyclovir** may be of benefit in patients with meningitis caused by **HSV-1 or HSV-2** and in cases of severe **EBV or VZV infection.**
- Patients with **HIV** should receive highly **active antiretroviral therapy.**

Mollaret's Meningitis

Q. Write a short note on Mollaret's meningitis.

Definition: It is a syndrome characterized by recurrent aseptic, self-limiting meningitis and presence of large typical monocytes (Mollaret cells) in the CSF.

- **Cause:** Not known, but may be due to some virus infections. Herpes simplex-2 infection must be excluded in these patients.
- **Clinical features:** Repeated self-limiting episodes of fever, meningismus and severe headache (of 2–5 days duration) separated by symptom-free intervals.

Noninfective causes of meningitis are listed in **Table 16.36**.

TABLE 16.36: Noninfective ("sterile") causes of meningitis.

Type of noninfectious meningitis	*Causes*
Carcinomatous	Leukemia, lymphoma, myeloma, melanoma, breast and lung cancer
Connective tissue disorders	Behçet's, SLE, sarcoid, rheumatoid, Sjogren's
Drugs	Azathioprine, cyclosporine, sulfasalazine
Substances injected into the subarachnoid space	Anesthetics, antibiotics, chemotherapy drugs, radiopaque contrast agents

CSF Findings in Meningitis (Table 16.37)

Q. PE30.2 Distinguish bacterial, viral and tuberculous meningitis.

TABLE 16.37: CSF findings in meningitis.

	Normal	*Acute pyogenic*	*Acute viral (aseptic)*	*Tuberculous*
Physical examination	Clear and colorless	Turbid and forms coagulum	Clear	Clear and colorless, forms cobweb on standing due to coagulation of fibrinogen
CSF pressure	60–150 mm of H_2O	Raised >180 mm of H_2O	Raised >250 mm of H_2O	Raised >300 mm of H_2O
Total protein	20–40 mg/100 mL (<0.45 g/L)	>50–200 mg/100 mL	>40 mg/100 mL	50–150 mg/100 mL
Glucose	45–80 mg/100 mL (>50–60% of blood level)	0–20 mg/100 mL (usually <40 mg/dL)	Normal	Decreased: May be <45 mg/100 mL
Chlorides	720–750 mg/100 mL	600–700 mg/100 mL	Normal	450–600 mg/100 mL
Cells				
Polymorphs	Usually absent	1,000–5,000/mL	Absent	0–5 cells/μL
Lymphocytes	0–5 cells/μL	5–50 cells/μL	10–2,000 cells/μL	50–5,000 cells/μL
Gram stain/Ziehl–Neelsen (ZN) stain	–	Bacteria +	–	AFB + (ZN stain/auramine stain) or tuberculosis culture positive

Causes of Neck Stiffness (Box 16.30)

Q. List the causes of neck stiffness.

Box 16.30: Causes of neck stiffness.

Meningism:
- Meningitis
- Subarachnoid hemorrhage

Other conditions that mimic meningism (also resist cervical rotation):
- Cervical spondylosis
- After cervical fusion
- Parkinson's disease
- Raised intracranial pressure especially if there is impending tonsillar herniation
- Acute dystonic reaction
- Tetanus
- Strychnine poisoning

Intermittent neck stiffness is characteristic of Arnold–Chiari malformation

Encephalitis

Q. MI5.2 Describe the etiopathogenesis, clinical course and discuss the laboratory diagnosis of encephalitis.

Viral Encephalitis

- In meningitis, the infectious process and associated inflammatory response is limited largely to the meninges, whereas in encephalitis, the brain parenchyma is also involved.
- Encephalitis is characterized by nonsuppurative inflammation of brain by an inflammatory process.

Etiology

See **Box 16.31**

Clinical manifestations

- Acute febrile illness with evidence of meningitis and encephalitis.
- Altered level of consciousness (ranging from mild lethargy to coma), an abnormal mental state, and evidence of either focal or diffuse neurologic signs or symptoms.
- It may have hallucinations, agitation, personality change, behavioral disorders and at times a frankly psychotic state.
- Focal or generalized seizures occur in many patients with encephalitis.

- **Most common focal neurological findings:** Aphasia, ataxia, upper or lower motor neuron patterns of weakness, involuntary movements (e.g., myoclonic jerks, tremor), and cranial nerve deficits (e.g., ocular palsies, facial weakness).
- Involvement of the hypothalamic pituitary axis may result in temperature dysregulation, diabetes insipidus, or the development of the syndrome of inappropriate secretion of antidiuretic hormone (SIADH).

Box 16.31: Viruses causing encephalitis.

- Epidemics of encephalitis are caused by arboviruses
- Acute encephalitis
- Herpes virus
  - Herpes simplex virus I (MC)
  - Varicella zoster virus
  - Epstein–Barr virus
- Arthropod-borne viruses
- West Nile virus
- Japanese encephalitis Colorado tick fever
- **Others:** Rabies, enteroviruses, mumps, cytomegalovirus

Laboratory diagnosis

1. **Cerebrospinal fluid**
   - *CSF examination:* Indistinguishable from that of viral meningitis and typically consists of lymphocytic pleocytosis, a mildly elevated protein concentration, and a normal glucose concentration.
   - *CSF PCR:* Primary diagnostic test for CNS infections caused by CMV, EBV, HHV-6 and enteroviruses.
   - *CSF culture:* Limited utility.
2. **Serologic studies and antigen defection:** Demonstration of antibodies or antigens.
3. **Brain biopsy:** Reserved for patients in whom CSF PCR studies fail to lead to a specific diagnosis, who have focal abnormalities on MRI, and who continue to show progressive clinical deterioration despite treatment with acyclovir and supportive therapy.
4. **MRI, CT and EEG**.

Management

- **General measures:** Care of the unconscious patient. Anticonvulsants may be needed. Brain edema is managed with dexamethasone 4 mg 6 hourly.
- **Herpes simplex encephalitis:** Acyclovir (10 mg/kg IV 8 hourly for 14–21 days), if instituted early.

Froin's Syndrome

Q. Write a short note on Froin's syndrome.

- Froin's syndrome describes the CSF findings in cases of complete spinal (subarachnoid) block (below the block).
- **CSF below the block** shows following features:
  - *CSF pressure:* Reduced
  - *Queckenstedt's test:* It is an outdated clinical test, formerly used for diagnosing spinal block.
  - *Physical examination:* Yellowish discoloration (xanthochromia) coagulum may form due to high protein content.
  - *Chemical examination:* Very much elevation of protein levels, sugar levels are normal or occasionally reduced if the obstruction is due to tuberculous meningitis.
    - Cytology: Normal cell count. Increased cells if the obstruction is due to tuberculous meningitis.
- **Causes of total block:**
  - Intraspinal tumors
  - Vertebral disease with compression.
  - Chronic spinal arachnoiditis.

Neurosyphilis

Q. Write a short essay on the clinical features and management of neurosyphilis.

- *Treponema pallidum* invades nervous system within 3–18 months (may take years to develop) after primary infection.
- **Neurosyphilis** may be asymptomatic or symptomatic. Initial event is usually in the form of asymptomatic meningitis. Later it may produce more damage. All forms of neurosyphilis have meningitis of variable severity. Secondary to meningitis, the blood vessels show endarteritis obliterans.

Asymptomatic Neurosyphilis

- Asymptomatic invasion of CNS by treponema is common and occur within few months of primary infection by *Treponema pallidum.*
- Neurosyphilis may develop in 25% cases of latent syphilis. Many of them may develop symptomatic neurosyphilis.

- Cerebrospinal fluid shows lymphocytosis with increased protein and low glucose. Antibodies in the CSF, is the most specific test for neurosyphilis. Venereal disease research laboratory test is positive.
- **Treatment:** Penicillin.

Symptomatic Neurosyphilis

It takes one of several forms, although mixed features are common **(Box 16.32)**.

Meningeal syphilis

- Symptoms of meningitis may develop at any time after infection, but usually occur within 2 years after primary infection.
- **Symptoms:**
  - These include headache, neck stiffness, seizures, altered sensorium and cranial nerve palsies. It may show skin rash on palms and soles.
  - Papilledema with symptoms of increased ICP may develop.
  - Patient is afebrile and CSF is abnormal.

Meningovascular syphilis

- Chronic meningitis involves base of the brain, cerebral convexities and spinal leptomeninges.
- Usually presents 6–7 years after primary infection. However, it can develop as early as 6 months and as late as 10–12 years.
- It should be suspected when a young patient develops stroke (generally subacute) which results in hemiparesis, aphasia, visual loss, etc. Other features include headache, vertigo, insomnia, and psychological abnormalities.

  Cerebrospinal fluid findings in neurosyphilis have been shown in **Table 16.38**.

Box 16.32: Major categories of symptomatic neurosyphilis.

- Meningeal syphilis
- Chronic meningovascular disease
- Parenchymatous syphilis
  - General paresis of insane
  - Tabes dorsalis

TABLE 16.38: CSF findings in neurosyphilis.

Parameter	*Findings*
Pressure	Normal or raised
CSF fluid	Clear
Protein	Raised (100–200 mg%)
Glucose	Normal
Cell count	Mildly elevated and cells are lymphocytes
Gamma-globulin levels	Raised
Venereal disease research laboratory (VDRL)	Positive
Fluorescent treponemal antibody absorption (FTA-ABS)	Positive

Note: Gold standard test for diagnosis is VDRL from CSF. This is highly specific but only 30–70% sensitive for neurosyphilis. CSF FTA-ABS is more sensitive but not specific because false-positives are common.

General paralysis of insane

- It develops about 20 years after primary infection.
- Shows generalized/diffuse brain parenchymal disease with **dementia**; hence called as general paresis of insane.
- Clinical manifestation includes personality changes, illusions, delusions, hallucinations, dementia (reduced memory), hyperactive reflexes and Argyll Robertson pupils.

Tabes dorsalis

- Tabes dorsalis is the parenchymal form of neurosyphilis characterized by **demyelination of posterior column, dorsal root and dorsal root ganglia** in the spinal cord.
- Usually develops 20–25 years after primary infection.
- **Symptoms:** Severe lightening pains in trunk and extremities, ataxia and urinary incontinence.
- **Signs:** Patchy tactile sensory loss and severe impairment of proprioception with sensory ataxia. Muscular strength is normal and tendon jerks are absent. Complications include trophic lesions such as perforating ulcers of feet and Charcot's joints. Argyll Robertson pupils may also be observed in tabes dorsalis.
- **Visceral crisis:** It consists of sudden epigastric pain with vomiting that Abadie's sign (Pinching of, or the application of firm pressure to, the Achilles tendon does not result in pain) lasts for hours. Barium studies show pylorospasm (gastric crisis). Other crisis includes intestinal crisis with diarrhea, rectal crisis with tenesmus, genitourinary crisis with strangury and pharyngeal-laryngeal crisis with gulping movements and dyspnea.
- CSF findings (*refer* **Table 16.34**).

Treatment

- **Penicillin:** Drug of choice and given in the dose of 18–24 million units/day for 15–20 days.
- If patient is sensitive to penicillin: Erythromycin and tetracycline 0.5 g 6 hourly for 20–30 days.

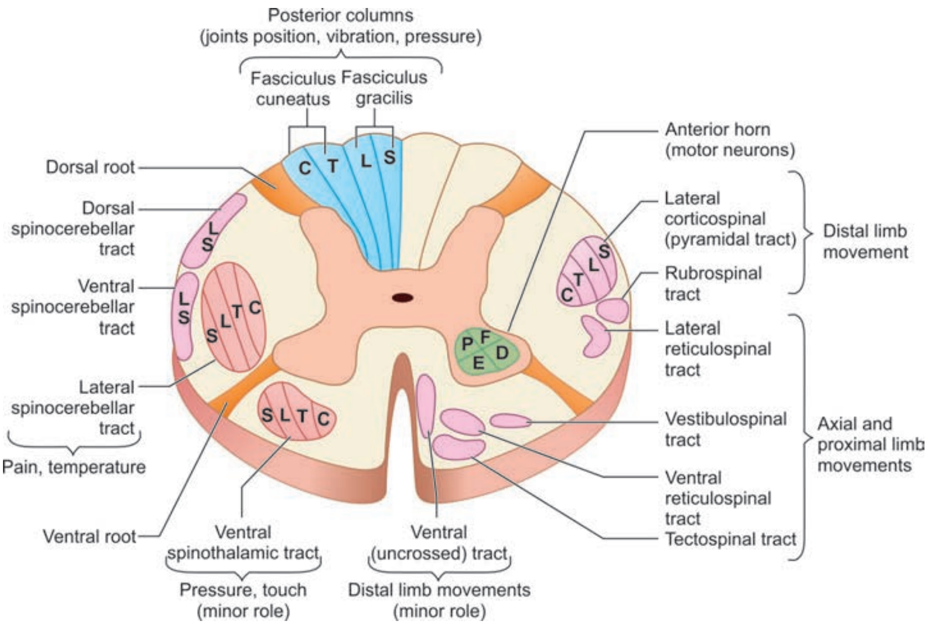
Follow-up

- Re-examine the patient every 3 months and CSF examination at 6 months interval.
- If CSF is normal and VDRL titers are reduced, no further treatment is necessary. However, if CSF remains abnormal, patient should be treated by another full course of penicillin.

DISEASES OF THE SPINAL CORD

Features Suggestive of Spinal Cord Involvement (Fig. 16.19 and Box 16.33)

Q. List the spinal cord syndrome with examples.



Posterior columns
(joints position, vibration, pressure)
Fasciculus cuneatus
Fasciculus gracilis
C T L S
Dorsal root
Dorsal spinocerebellar tract
Ventral spinocerebellar tract
Lateral spinocerebellar tract
Pain, temperature
Ventral root
Ventral spinothalamic tract
Pressure, touch (minor role)
Ventral (uncrossed) tract
Distal limb movements (minor role)
Anterior horn (motor neurons)
Lateral corticospinal (pyramidal tract)
Rubrospinal tract
Distal limb movement
Lateral reticulospinal tract
Vestibulospinal tract
Ventral reticulospinal tract
Tectospinal tract
Axial and proximal limb movements
L S
S L T C
S L T C
C T L S
P F E D

FIG. 16.19: Spinal cord anatomy.

Box 16.33: Features suggestive of spinal cord involvement.

- Presence of sensory deficit and/or motor weakness in both lower limbs and/or upper limbs
- Bladder and bowel involvement
- Brown–Sequard type of clinical picture
- Presence of definite sensory level

Patterns of Spinal Cord Disease (Box 16.34)

Box 16.34: Patterns of spinal cord disease.

- Complete cord transection syndrome (trauma)
- Brown–Sequard syndrome (bullet injury, multiple sclerosis)
- Central cord syndrome (syringomyelia)
- Posterior column syndrome (tabes dorsalis, Friedreich's ataxia, HIV myelopathy)
- Posterolateral cord syndrome—subacute combined degeneration of the cord (SACDC)
- Combined anterior horn cell (AHC) and pyramidal tract syndrome [amyotrophic lateral sclerosis (ALS)]
- Anterior horn cell syndrome (polio)
- Anterior cord syndrome (anterior spinal artery occlusion)
- Conus medullaris and cauda equina syndrome

Causes and Clinical Features of Spinal Cord Syndromes (Table 16.39)

TABLE 16.39: Causes and clinical features of spinal cord syndromes.

Complete cord transection (Fig. 16.20) *Causes* ➢ Trauma ➢ Metastatic carcinoma ➢ Multiple sclerosis ➢ Spinal epidural hematoma ➢ Autoimmune disorders ➢ Postvaccinial syndromes  **FIG. 16.20:** Complete cord transection.	➢ Sensory – All sensations are affected – Sensory level is usually 2 segments below the level of lesion – Segmental paresthesia occurs at the level of lesion ➢ Motor – Paraplegia due to corticospinal tract involvement – First spinal shock followed by hypertonic hyperreflexia paraplegia – Loss of abdominal and cremasteric reflexes – At the level of lesion, lower motor neuron (LMN) signs occur ➢ Autonomic – Urinary retention and constipation – Anhidrosis, trophic skin changes, vasomotor instability below the level of lesion – Sexual dysfunction can occur

Contd...

Contd...

Brown–Sequard syndrome (Fig. 16.21) ➢ Due to damage to one lateral half of spinal cord – Caused by extramedullary lesions – Usually caused by penetrating injuries (Gunshot) or tumor  **FIG. 16.21:** Brown-Sequard syndrome.	➢ Sensory – Ipsilateral loss of proprioception due to posterior column involvement – Contralateral loss of pain and temperature due to involvement of lateral spinothalamic tract 1 or 2 segments below ➢ Motor – Ipsilateral spastic weakness due to descending corticospinal tract involvement – Lower motor neuron (LMN) signs at the level of lesion
Central cord syndrome (Fig. 16.22) ➢ Most common cause is syringomyelia ➢ Other causes are hyperextension injuries of neck, intramedullary tumors and trauma ➢ Associated with Arnold–Chiari type 1 and 2 and Dandy–Walker malformation  **FIG. 16.22:** Central lesions (syringomyelia).	➢ Sensory – Pain and temperature are affected – Touch and proprioception are preserved – Dissociative anesthesia – Shawl-like distribution of sensory loss ➢ Motor – Upper limb weakness > lower limb weakness ➢ Other features include – Horner's syndrome – Kyphoscoliosis – Sacral sparing – Neuropathic arthropathy of shoulder and elbow joint – Early bladder involvement (exception—syringomyelia)
Posterior column syndrome (Fig. 16.23) ➢ Occurs due to neurosyphilis, diabetes mellitus  **FIG. 16.23:** Posterior column syndrome.	➢ Sensory – Impaired position and vibration sense in lower limbs – Sensory ataxia – Positive Romberg's sign, sink sign, and Lhermitte's sign ➢ Abadie's sign positive ➢ Urinary incontinence ➢ Absent knee and ankle jerk (areflexia, hypotonia) ➢ Charcot's joint ➢ Miotic and irregular pupil not reacting to light—Argyll Robertson pupil
Posterolateral column disease (Fig. 16.24) ➢ Vitamin B_{12} deficiency ➢ AIDS ➢ HTLV-associated myelopathy ➢ Cervical spondylosis  **FIG. 16.24:** Posterolateral column syndrome tabes dorsalis.	➢ Sensory – Paresthesia in feet – Loss of proprioception and vibration in legs – Sensory ataxia – Positive Romberg's sign ➢ Bladder atonia ➢ Motor – Corticospinal tract involvement—spasticity, hyperreflexia, bilateral Babinski's sign ➢ AIDS-associated dementia and spastic bladder is present ➢ HTLV-associated myelopathy—slowly progressive paraparesis and an increase in CSF IgG antibodies to HTLV1

Contd...

Contd...

Anterior horn cell syndrome (Fig. 16.25) ➤ Spinal muscular atrophy (SMA)  FIG. 16.25: Anterior horn cell syndrome.	➤ Motor – Weakness, atrophy, and fasciculations – Hypotonia with depressed reflexes – Muscles of trunk and extremities are affected ➤ Sensory system is not affected
Anterior spinal artery syndrome (Fig. 16.26) ➤ Occurs due to syphilitic arteritis, aortic dissection, atherosclerosis of aorta, systemic lupus erythematosus (SLE), AIDS, arteriovenous malformation (AVM)  FIG. 16.26: Anterior spinal artery occlusion.	➤ Motor – Flaccid and areflexic paraplegia ➤ Sensory – Loss of pain and temperature – Preservation of position and vibration ➤ Autonomic – Urinary incontinence – Spinal cord infarction usually occurs in T1–T4 and L1 segment – Abrupt onset, radicular or girdle pain
Posterior spinal artery syndrome ➤ Rare	➤ Loss of proprioception and vibratory sense ➤ Pain and temperature are preserved ➤ Absence of motor deficit
Anterior horn cell and pyramidal tract (Fig. 16.27) ➤ Amyotrophic lateral sclerosis (ALS)  FIG. 16.27: Combined anterior horn cell—pyramidal tract syndrome (amyotrophic lateral sclerosis).	➤ Lower motor neuron (LMN) signs ➤ Upper motor neuron (UMN) signs ➤ Sensations preserved ➤ Onuf's nucleus spared: hence no bladder and bowel involvement

Q. List the differences between compressive and noncompressive myelopathy.

The differences between compressive and noncompressive myelopathy are presented in **Table 16.40**.

TABLE 16.40: Differences between compressive and noncompressive myelopathy.

Features	***Compressive***	***Noncompressive***
Bony deformity	+	–
Bony tenderness	+	–
Girdle-like sensation	+	–
Upper level of sensory loss	+	–
Zone of hyperesthesia	+	–
Root pain	+	–
Onset and progress	Gradual	May be acute
Symmetry	Symmetrical	Majority are asymmetrical
Flexor spasm	Common	Usually absent
Pattern of neurodeficit	U-shaped (Elsberg phenomenon)	Bilaterally symmetrical
Bladder and bowel movement	Late	Early (acute transverse myelitis)
Classical example	Tuberculosis of spine	Acute transverse myelitis, motor neuron disease (chronic)

Q. Write a short essay on differences between extramedullary and intramedullary lesions of the spinal cord.

The differences between extramedullary and intramedullary lesions of the spinal cord are listed in **Table 16.41**.

TABLE 16.41: Differences between extramedullary and intramedullary lesions of the spinal cord.

Features	*Extramedullary*	*Intramedullary*
Root pain	Early and common	Rare, pain is burning in type and poorly localized
Secondary deficit	No dissociation of sensation, contralateral loss of pain and temperature, with ipsilateral loss or proprioception	Dissociation of sensation common, suspended sensory loss
Sacral sensation	Lost (early)	Sacral sparing
Lower motor neuron (LMN) involvement	Segmental	Marked with wide spread atrophy, fasciculation seen
Upper motor neuron (UMN) involvement	Early and prominent. Ascending pattern of weakness (sacral → lumbar → thoracic → cervical)	Less pronounced, late feature, descending pattern
Reflexes	Brisk early feature	Less brisk, later feature
Autonomic involvement (bladder and bowel)	Late	Early
Trophic changes	Usually not marked	Common
Vertebral tenderness	May be sensitive to local pressure	No bony tenderness in vertebrae
Changes in CSF	Frequent	Rare

The differences between presentation of intradural and extradural lesion are presented in **Table 16.42**.

TABLE 16.42: Differences between presentation of intradural and extradural lesion.

Features	*Extradural*	*Intradural*
Mode of onset	Usually symmetrical	Asymmetrical
Root pain	Less common	More common
Spinal tenderness	Common	Uncommon
Spinal deformity	Present	Absent

Causes of Compressive Myelopathies (Table 16.43)

Q. Write a short note on common causes of compressive myelopathies.

TABLE 16.43: Causes of compressive myelopathies.

Extradural	*Intradural*	*Intramedullary*
➢ Spondylosis ➢ Disk prolapse ➢ Trauma ➢ Tumor: Metastasis, multiple myeloma ➢ Craniovertebral junction (CVJ) anomalies ➢ Fluorosis ➢ TB spine ➢ Epidural abscess ➢ Epidural hematoma	➢ Tumor: Neurofibroma, meningioma, lipoma, sarcoma metastasis ➢ Arachnoiditis ➢ Sarcoidosis ➢ Cervical meningitis ➢ Arteriovenous malformation ➢ Leukemic infiltration ➢ Arachnoid cyst	➢ Syrinx ➢ Tumor: Ependymoma, astrocytoma, hemangioblastoma, hematomyelia

Localization of the level of lesion in a compressive myelopathy

- **Distribution root pain:** Ask for specific dermatomes involved.
- **Upper border of sensory loss:** Examine the patient from below upward for demonstration of upper border of sensory loss (spinothalamic tract).
- Girdle like sensation or sense or constriction at the level of lesion (involvement of posterior column).
- Zone of hyperesthesia or hyperalgesia (zone of hyperesthesia is present just above the level of girdle like sensation, and is due to compression of posterior nerve roots.
- **Analysis of abdominal reflex:** If upper abdominal reflex is intact with loss of middle and lower one, the site of lesion is probably at T10 spinal segment.
- **Atrophy of the muscles in a segmental distribution** (due to anterior horn cells).
- **Loss of deep reflexes:** If the particular segment is involved. The reflexes will be brisk below the involved segment.
- Deformity or any swelling in the vertebra
- Tenderness in the vertebra
- The area of sweating may help (lack of sweating below the level) in localizing the level of lesion.
- The level can also be localized by X-ray of the spine, myelography, CT scan or MRI.

Beevor's Sign

- **Analysis of Beevor's sign:** It is medical sign seen in the selective weakness of the lower abdominal muscles. Rectus abdominis is innervated by the terminal branches lower six or seven thoracic spinal nerves via the lower intercostal and subcostal nerves. If a lesion lies above T6, entire rectus abdominis is weak so there is no contraction of muscle. If it is at or below T10, the upper abdominal muscular function is preserved, whereas the lower abdominal muscles are weak. Therefore, when the head is flexed against resistance (patient supine), the intact upper abdominal muscles pull the umbilicus upward and shift of umbilicus 3 cm when head flexed is considered significant.

- **Causes of Beevor's sign:**
    - Amyotrophic lateral sclerosis
    - Facioscapulohumeral muscular dystrophy (FSHD)
    - Adult form of acid maltase deficiency disease
    - Spinal cord injury
    - Myopathy

Q. List the differences between paraplegia in flexion, paraplegia in extension.

The differences between paraplegia in flexion and paraplegia in extension are listed in **Table 16.44**.

TABLE 16.44: Differences between paraplegia in flexion and paraplegia in extension.

Feature	***Paraplegia in extension***	***Paraplegia in flexion***
Definition	Lower limb muscles take an extension attitude and extensor muscles are spastic	Lower limb muscles take an attitude of flexion
Pathology	Only pyramidal tract involved	Both pyramidal and extrapyramidal tract involved. Occurs in late stage of paraplegia or progressive lesion and spinal arc is dominant
Evolution	Early	Late
Position of lower limbs	Extended	Flexed
Deep tendon reflexes	Exaggerated	Less exaggerated
Clonus	Present	Absent
Mass reflex	Absent	Present
Bladder	Precipitancy	Automatic bladder

Note: Pierre Marie–Foix test is done by firm passive plantar flexing of the toes and foot. This will result in spontaneous "withdrawal reflex", i.e., spontaneous flexion of the hip, knee and dorsiflexion of the ankle if the paraplegia is passing from extension to flexion.

Flexor Spasms

- After recovery from spinal shock, many types of innocuous or noxious cutaneous or muscle stimuli to the lower limb can elicit a prolonged, coordinated pattern of hip flexion and ankle dorsiflexion, similar to flexion withdrawal. It is attributed to increased hyperexcitability of spinal cord circuitry and lead to flexor spasms.
- Spinal cord lesions are associated with flexor spasms except for incomplete and high spinal cord lesion that usually have dominant extensor tone.

Acute and Subacute Spinal Cord Diseases

Spinal Cord Compression

Q. Write a short note on causes of extramedullary spinal cord compression.

- Spinal cord compression is one of the common neurological emergencies in clinical practice.
- **Mechanism of damage:** A space-occupying lesion within the spinal cord may damage nerve tissue either by **direct pressure** or indirectly by **interfering with blood supply**. Edema due to venous obstruction impairs neuronal function, and ischemia due to arterial obstruction may causes necrosis of the spinal cord.
- **Consequences:** During early stages, the damage is reversible but severely damaged neurons cannot recover. Hence, it is important to diagnose and treat early.
- Various causes of spinal cord compression are listed in **Box 16.35**.

Box 16.35: Causes of spinal cord compression.

Vertebral (80%)
- Vertebral body destruction by bone metastases, e.g., breast, prostate, bronchus, myeloma
- Disk and vertebral lesions: Trauma (extradural), chronic degenerative, and acute central (intervertebral) disk prolapse
- Inflammatory: Tuberculosis, Staphylococcus aureus, melioidosis

Meninges (intradural, extramedullary) (15%)
- Tumors (e.g., meningioma, neurofibroma, ependymoma, metastasis, lymphoma, leukemia)
- Inflammatory: Epidural abscess, epidural hemorrhage/hematoma

Spinal cord (intradural, intramedullary) tumors (5%)
- Extramedullary, e.g., meningioma or neurofibroma, metastasis
- Intramedullary, e.g., glioma or ependymoma

Investigations

Patients with acute or subacute spinal cord syndrome should be investigated urgently.

- **MRI of spine:** MRI is the investigation of choice. MRI can define the extent of compression and associated abnormality in the soft tissue.
- **Plain X-rays of spine:** It may show destruction of bone and soft tissue abnormalities.
- **Chest X-ray:** It may show evidence of systemic disease
- Myelography
- **CSF:** If there is complete spinal block, CSF shows a normal cell count with a raised protein causing yellow discoloration of the fluid (Froin's syndrome).
- Serum vitamin B_{12}
- **Biopsy:** If a secondary tumor is causing the cord compression, needle biopsy may be established diagnosis.

Symptoms and signs of spinal cord compression

See **Box 16.36.**

Box 16.36: Symptoms and signs of spinal cord compression.

Symptoms of spinal cord compression

- **Pain:** Occurs early. Localized over the spine or in a root distribution. May be aggravated by coughing, sneezing or straining
- **Sensory:** Occurs early. Paresthesia, numbness or cold sensations (especially in the lower limbs), spread proximally to a level on the trunk
- **Motor:** Occurs late. Weakness, heaviness or stiffness of the limbs (commonly legs)
- **Sphincters:** Occurs late. Urgency or hesitancy of micturition, and retention of urine

Signs of spinal cord compression: Vary according to the level of the cord compression and the structures involved

Cervical, above C5: Frequently life threatening

- Upper motor neuron signs and sensory loss in all four limbs (quadriplegia)
- Weakness of diaphragm (phrenic nerve)

Cervical, C4–C5: Quadriplegia with preserved respiratory function

Cervical, C5–T1

- Lower motor neuron (LMN) signs and segmental sensory loss in the arms; upper motor neuron (UMN) signs in the legs
- Weakness of respiratory (intercostal) muscle

Thoracic cord

- Spastic paraplegia with a sensory level on the trunk
- Weakness of legs, sacral loss of sensation and extensor plantar responses
- Midline back pain is a useful localizing sign

Lumbar cord and Cauda equina

- Spinal cord ends at the T12/L1 spinal level. Spinal lesions below this level can cause only LMN signs by affecting the cauda equina
- L1–L2—cremasteric reflex is a cutaneous reflex useful in localization of lumbar cord disease
- L2–L4 paralyzes flexion and abduction of the thigh, weakens leg extension at the knee, and abolishes the patellar reflex
- L5–S1 paralyzes movements of the foot and ankle, flexion at the knee, and extension of the thigh, and abolishes the ankle jerk (S1)

Brown–Séquard Syndrome

Q. Write a short note on the causes and clinical manifestations of Brown–Séquard syndrome.

It refers to findings seen when the damage is confined to one side (lateral half) of the spinal cord. With compressive lesions, there is a band of pain at the level of the lesion in the distribution of the nerve roots involved by compression.

Causes: Due to extramedullary lesions, usually caused by penetrating injuries (gunshot) or tumor.

Management

- Treatment depends on the underlying lesion.
- Benign tumors should be surgically excised.
- Extradural compression due to malignancy has a poor prognosis. Useful function can be regained if treatment (e.g., radiotherapy), is started within 24 hours of the onset of severe weakness or sphincter dysfunction.
- Spinal cord compression due to tuberculosis may require surgical treatment and antituberculous chemotherapy.
- Traumatic lesions of the vertebral column needed treatment by neurosurgeon.

Clinical Features

- Sensory
  - Ipsilateral loss of proprioception due to posterior column involvement
  - Contralateral loss of pain and temperature due to involvement of lateral spinothalamic tract.
- Motor
  - Ipsilateral spastic weakness due to descending corticospinal tract involvement
  - Lower motor neuron signs at the level of lesion.

Chronic Myelopathies

Syringomyelia

Q. Write a short essay on the pathogenesis of syringomyelia.

- A syrinx is a fluid-filled cavity within the spinal cord. Syringomyelia is a **cavitary expansion of the spinal cord**. Syrinxes commonly develop in the lower cervical and high thoracic regions or in the high cervical region. They may extend proximally to the medulla or pons (syringobulbia).

- **Pathogenesis:** More than 50% are associated with Arnold–Chiari type I malformation characterized by herniation of cerebellar tonsils through the foramen magnum. This abnormality at the foramen magnum probably allows normal pulsatile CSF pressure waves to be transmitted to fragile tissues of the cervical cord and brainstem. This results in secondary cavity formation. There is gradually destruction of spinothalamic neurons, anterior horn cells and lateral corticospinal tracts. It leads to progressive myelopathy.
- **Classic presentation** is a central cord syndrome with dissociated sensory loss and areflexic weakness in the upper limbs.
- **Sensory loss:** Most cases begin asymmetrically with unilateral sensory loss. The sensory loss has a distribution that is "suspended" over the nape of the neck, shoulders, and upper arms (cape distribution) or in the hands.
- Neurogenic arthropathies **(Charcot's joint):** Most common in shoulder. Thoracic kyphoscoliosis is common.
- **La main succulente of syringomyelia** (subcutaneous thickening and swollen fingers).
- **Morvan's syndrome:** Progressive loss of pain sensation, ulceration, loss of soft tissues and resorption of phalanges.
- **MRI scans (Fig. 16.28):** Accurately identify syrinx cavities and associated spinal cord enlargement.
- **Treatment is surgery:** Posterior decompression of Arnold–Chiari malformation and the coperitoneal shunt to drain syrinx cavity.

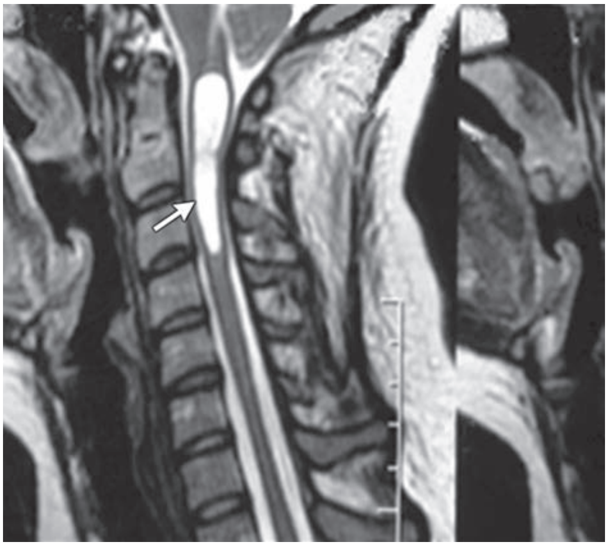


FIG. 16.28: MRI showing cervical syringomyelia.

Syringobulbia

It is characterized by dysphagia, nystagmus, pharyngeal and palatal weakness, asymmetric weakness and atrophy of the tongue, and loss of pain, temperature in the distribution of the trigeminal nerve (facial sensory loss resembling in distribution a **balaclava helmet),** involving the outer parts of the face but sparing the nose and mouth. This pattern of facial sensory impairment may also be known as onion-peel or onion-skin pattern.

Subacute Combined Degeneration of Cord

Q. Write a short essay on etiology, clinical features/neurological signs and management of subacute combined degeneration (SACD).

It is myelopathy that develops due to nutritional deficiency of vitamin B_{12} deficiency, including pernicious anemia.

- This treatable myelopathy presents with paresthesia in the hand and feet, early loss of vibration and position sensation, and a progressive spastic and ataxic weakness.
- Loss of reflexes due to a superimposed peripheral neuropathy in a patient who also has Babinski's sign is an important diagnostic clue.
- The myelopathy of SACD tends to be diffuse rather than focal; signs are generally symmetric and reflect predominant involvement of the posterior and lateral tracts.
- Optic atrophy and irritability prominent in advanced cases.
- **Low vitamin B_{12}** levels confirm the **diagnosis**.
- **MRI spinal cord:** Inverted V sign or rabbit ear sign due to T2 hyper-intensity along posterolateral column of spinal cord.

Treatment is by replacement therapy, beginning with 100 mg of intramuscular vitamin B_{12} repeated at regular intervals or by subsequent oral treatment.

Causes of posterior column disease ***(Box 16.37)***

Q. Write a short essay on diseases affecting posterior column. Explain clinical features of any one of them.

Refer respective diseases.

Paraplegia

Q. Write a short note on causes and differential diagnosis of spastic paraplegia.

Paraplegia is weakness or paralysis of both lower limbs, sparing the upper limbs.

Box 16.37: Causes of posterolateral column disease.

- Vitamin B_{12} deficiency
- AIDS
- HTLV-associated myelopathy
- Cervical spondylosis, hypocupremia, vitamin E deficiency

Causes: It can occur in disorders of cerebrum, spinal cord, spinal roots, peripheral nerves or muscles. It is usually due to disorders of spinal cord.

Spastic Paraplegia

Spasticity is due to an upper motor neuron lesion. It is usually produced to subacute or chronic lesion. Acute lesions usually cause flaccid paralysis.

Causes of spastic paraplegia **(Table 16.45)**

TABLE 16.45: Causes of spastic paraplegia [upper motor neuron (UMN) type lesion].

A. Gradual onset	***B. Sudden onset***
Cerebral causes	
➢ Parasagittal meningioma ➢ Hydrocephalus	Thrombosis of unpaired anterior cerebral artery or superior sagittal sinus
Spinal causes	
Compressive or transverse lesion in the spinal cord: Cord compression **Noncompressive or longitudinal lesion** or systemic disease of the spinal cord ➢ Motor neuron disease (MND), e.g., amyotrophic lateral sclerosis ➢ Multiple sclerosis, Friedreich's ataxia ➢ Subacute combined degeneration (i.e., from vitamin B_{12} deficiency) ➢ Lathyrism, syringomyelia, Erb's spastic paraplegia, tropical spastic paraplegia ➢ Radiation myelopathy	**Compressive causes** ➢ Injury to the spinal cord (fracture-dislocation or collapse of the vertebra) ➢ Intervertebral disk prolapse ➢ Spinal epidural abscess or hematoma **Noncompressive causes** ➢ Acute transverse myelitis ➢ Thrombosis of anterior spinal artery ➢ Hematomyelia (from arteriovenous malformation, angiomas, or endarteritis)

Cauda Equina Syndrome

The **epiconus** comprises the cord segment between L4 and S1, corresponding to the T12 and L1 vertebrae. The most distal bulbous part of the spinal cord (L1–L2) is called the conus medullaris. The **conus medullaris** consists of the cord segment between S2 and S5 as well as coccygeal segments. Distal to this end of the spinal cord is a collection of nerve roots (L2–L3 onward to coccygeal), which are horsetail-like in appearance called the **cauda equina (Table 16.46 and Fig. 16.29)**.

TABLE 16.46: Differences between conus medullaris and cauda equina syndromes.

Features	***Conus medullaris syndrome***	***Cauda equina syndrome***
Presentation	Sudden and bilateral	Gradual and unilateral
Reflexes	Knee jerks preserved but ankle jerks affected	Both knee and ankle jerks affected
Radicular pain	Less severe	More severe
Low back pain	More	Less
Sensory symptoms and signs	Numbness in symmetrical and bilateral, sensory dissociation occurs. Saddle anesthesia present	Numbness is asymmetrical, may be unilateral, no necessary dissociation
Motor strength	Typically symmetric, hyperreflexic distal paresis of lower limbs	Asymmetric areflexic paraplegia
Impotence	Frequent	Less frequent
Sphincter dysfunction	Overflow urinary incontinence and fecal incontinence, tends to present early in course of disease	Urinary retention, tends to present late in course of disease

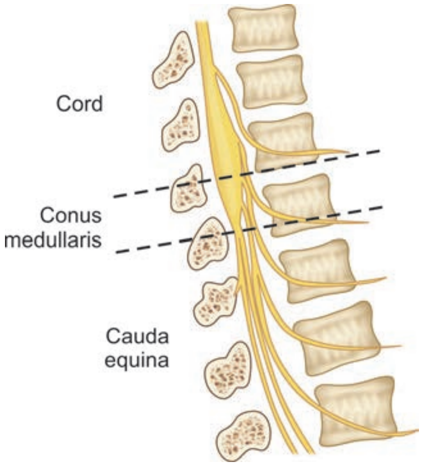

FIG. 16.29: Cord segment—conus medullaris and cauda equina.

Q. Write a short note on differences between conus medullaris lesions and cauda equina lesions.

The differences between conus medullaris and cauda equina syndromes are listed in **Table 16.46**.

Complications of Paraplegia

See **Box 16.38**

Management of Paraplegia

- **Skin care:** Prevention of pressure sores. They develop due to loss of sensation and reduced blood supply. Following measures will be helpful:
  - Turn the patient every 2–4 hours to avoid pressure over bony prominences.
  - Keep the skin dry and clean.
  - Specially designed mattress like water or air-cushioned bed will be useful.
  - The patient should be prevented from lying on the side of the pressure sores. Needs aseptic care and may require skin grafting.
- **Bladder**
  - Aseptic intermittent catheterization. Indwelling catheter is not advisable as it predisposes to infection, reduces bladder capacity and promotes calculus formation.
  - Prompt treatment of urinary infections and maintenance of adequate fluid intake.
- **Bowel:** Laxative to prevent constipation. If fecal matter becomes hard, manual evacuation is done.
- **Paralysis**
  - Spasticity can lead to contractures and flexor spasms. Hence, regular passive movements of the limbs should be encouraged.
  - Posture should be such that flexion is prevented at joints.
  - Drug treatment of spasticity: Baclofen, diazepam and tizanidine. In severe spasticity, intrathecal baclofen via a pump or sectioning of the anterior roots (rhizotomy).
- **Rehabilitation:** Use a caliper or wheelchair and physiotherapy.

Box 16.38: Complications of paraplegia.

- Pressure/bed sore
- Urinary infection and renal stones
- Fecal impaction with intestinal obstruction
- Contracture of limbs
- It may lead to death

Spinal Pain

Q. Discuss the different types of spinal pain.

- **Radicular pain:**
  - It is **unilateral, lancinating, dermatomal** pain often exacerbated by cough, sneeze, or Valsalva maneuver.
  - Common with **extradural growths** (e.g., neurilemmoma which is intradural extramedullary) and rare with intramedullary lesions.
- **Vertebral pain:**
  - It is an **aching pain localized to the point of the spine involved** in the compressive process and often accompanied by point tenderness.
  - Common with **neoplastic or inflammatory extradural lesions** and infrequent with intramedullary or intradural extramedullary lesions.
- **Funicular (central) pain:**
  - It is **deep, ill-defined painful dysesthesia**, usually distant from the affected spinal cord level (and therefore of poor localizing value), probably related to dysfunction of the spinothalamic tract or posterior columns.
  - It is common with **intramedullary lesions** and very unusual with extradural lesions.
- With dysfunction of the posterior columns in the cervical region, neck flexion may elicit a sudden "electric-like" sensation down the back or into the arms **(Lhermitte's sign or Barber's chair syndrome)**.
- More reliable band-like radicular pain or segmental paresthesia may occur at the level of the lesion and may be of localizing value for the appropriate spinal level.

Causes of Flaccid Paraplegia (LMN Type)

- **Upper motor neuron lesion in shock stage,** i.e., sudden onset or history of long duration as in extradural transverse myelitis and spinal injury
- **Lesion involving anterior horn cells**
  - Acute anterior poliomyelitis
  - Progressive muscular atrophy (a variety of motor neuron disease)
- **Diseases affecting nerve root**—tabes dorsalis, radiculitis, GBS
- **Diseases affecting peripheral nerves**
  - Acute infective polyneuropathy (GBS)
  - High cauda equina syndrome
  - Disease of peripheral nerves involving both the lower limbs
  - Lumbar plexus injury (psoas abscess or hematoma)

- **Diseases affecting myoneural junction**
  - Myasthenia gravis (MG), Lambert–Eaton syndrome
  - Periodic paralysis due to hypo- or hyperkalemia
- **Diseases affecting muscles:** Myopathy.

Causes of Pure Motor Paraplegia

See **Box 16.39**.

Causes of Quadriplegia (Table 16.47)

Weakness of all the 4 limbs can occur in the lesions from cortex to C5 level of spinal cord and various lower motor neuron lesion affecting anterior horn cells, roots, peripheral nerve, neuromuscular junction and muscles.

Craniovertebral Junction Anomalies

Q. Discuss craniovertebral junction (CVJ) anomalies.

- **Abnormal general physical appearance:** Head may be cocked to one side, short neck and scoliosis.
- **Neurological:** Most common posterior occipital headache that worsens with neck flexion or extension. Others include myelopathy and brainstem and lower cranial nerve deficits.
- **Vascular symptoms:** Intermittent attacks of altered consciousness, confusion, transient loss of visual fields and vertigo.

Classification of CVJ anomalies is presented in **Table 16.48.**

Hemiplegia

Q. Discuss hemiplegia in an elderly male. Give the differential diagnosis, investigations, and its treatment.

Hemiplegia is paralysis of one side of the body. Hemiparesis is the weakness of one side of body. For differential diagnosis, investigations and its treatment, refer individual diseases.

Causes of Hemiplegia

See **Table 16.49.**

Small Muscle Wasting of the Hand (Fig. 16.30)

Q. Write a short note on wasting of small muscles of hand.

Causes of Small Muscle Wasting of the Hand

See **Box 16.40**.

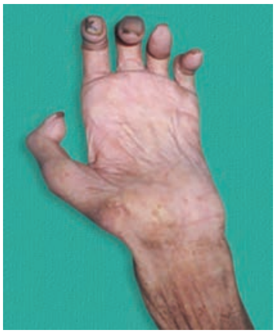

FIG. 16.30: Wasting of small muscles of hand.

Box 16.39: Causes of pure motor paraplegia.

- Hereditary spastic paraplegia
- Lathyrism
- Guillain–Barré syndrome
- Amyotrophic lateral sclerosis [motor neuron disease (MND)]
- Fluorosis
- Erb's spastic paraplegia (syphilitic)

TABLE 16.47: Causes of quadriplegia.

Upper motor neuron	*Lower motor neuron*
➢ Cerebral palsy	➢ Acute anterior poliomyelitis
➢ Bilateral brainstem lesion (glioma)	➢ Guillain–Barré syndrome
➢ Craniovertebral anomaly	➢ Peripheral neuropathy
➢ High cervical cord compression	➢ Myopathy or polymyositis
➢ Multiple sclerosis	➢ Myasthenia gravis and crisis
➢ Motor neuron disease	➢ Periodic paralysis
	➢ Snake bite, organophosphorus poisoning, etc.

TABLE 16.48: Craniovertebral junction anomalies.

Skeletal anomalies	*Neuraxial anomalies*
➢ Platybasia	➢ Arnold–Chiari malformation
➢ Basilar invagination (10/20)	➢ Dandy–Walker syndrome
➢ Klippel–Feil anomaly	➢ Occipitocervical myelomeningocele
➢ Occipitalization of atlas	➢ Posterior fossa cysts
➢ Atlantoaxial dislocation	

TABLE 16.49: Causes of hemiplegia.

Onset	*Causes*
Acute	
➢ Stroke	Cerebral infarct (thrombotic/embolic—most common cause in elderly), intracerebral hemorrhage (hypertensive), subarachnoid hemorrhage (SAH) with intracerebral hemorrhage
➢ Trauma	Hematoma (epidural or subdural), cerebral contusion
➢ Subacute	Meningitis, encephalitis, postseizure (Todd's paralysis)
➢ Chronic	Cerebral metastasis, subdural hematoma, granulomas (tuberculosis—younger age, fungal), pyogenic abscesses (metastatic infection, post-traumatic), rapidly growing malignant neoplasms (e.g., glioblastoma), hypoglycemia, multiple sclerosis, slow growing neoplasms

Box 16.40: Causes of small muscle wasting of the hand.

Lesions of vertebra: Craniovertebral anomalies, vertebral metastasis
Lesions of spinal cord: Syringomyelia, cord compression by tumor
Lesion of anterior horn cell: Motor neuron disease (MND), poliomyelitis
Lesions of spinal root: Cervical cord tumor, pancoast tumor, cervical disk prolapse
Lesion of brachial plexus: Cervical rib
Lesions of peripheral nerve: Hansen's disease, carpal tunnel syndrome, lead poisoning
Diseases of muscle: Distal muscular dystrophy, polymyositis
Disuse atrophy: Therapeutic immobilization (e.g., fracture), rheumatoid arthritis, postparalytic (hemiplegia)

MOTOR NEURON DISEASES

Q. Write a short essay/note on motor neuron disease.

Motor neuron disease (MND) is a devastating, progressive, **heterogeneous group** of **neurodegenerative** condition caused by loss of upper and lower motor neurons in the spinal cord, cranial nerve nuclei and motor cortex. There is no involvement of sensory or other nonmotor tracts. It causes progressive weakness and eventually death (usually as a result of respiratory failure or aspiration). Various types of MND are listed in **Table 16.50**.

TABLE 16.50: Various types of motor neuron disease.

Subset of motor neurons involved	*Clinical syndromes*
Upper motor neuron + lower motor neuron	Amyotrophic lateral sclerosis
Upper motor neuron	➢ Pseudobulbar palsy ➢ Primary lateral sclerosis ➢ Familial spastic paraplegia
Lower motor neuron	➢ Bulbar palsy ➢ Spinomuscular atrophy

Clinical Features

Q. Write a short answer on three neurological signs of upper and lower motor neuron disease.

There are four main clinical patterns. There is no involvement of sensory system. Hence, sensory symptoms (e.g., numbness, tingling and pain) are not present.

Amyotrophic Lateral Sclerosis

Q. Write a short essay/note on amyotrophic lateral sclerosis.

- Named by Jean Martin Charcot in 19th century. Also known as **Lou Gehrig's disease** after the famous baseball player diagnosed of ALS in 1930.
- Degeneration of the motor neuron (UMN and LMN) in motor cortex, brainstem and spinal cord.
  - *Amyotrophy:* Atrophy of muscle fibers consequent to denervation due to anterior horn cell degeneration.
  - *Lateral sclerosis:* Sclerosis of the anterior and lateral corticospinal tracts which are replaced by progressive gliosis. *Epidemiology:* Incidence is 1 to 2.7/lakh, prevalence is 2.7 to 7.4/lakh.
- **Sex predisposition:** M > F (2:1 to 7:1), (F > M in bulbar onset ALS).
- **Age:** Risk increases with age up to 74 years. Peak onset—6th to 7th decade (one to two decades earlier in India).
- **Prognosis:** 20% of patients survive for 5 years and 10% survive for 10 years.

Etiopathogenesis

- Undetermined etiology. Complex genetic and environmental interaction for neuronal degeneration.
- MND is usually (90–95%) sporadic.
- **Molecular pathway:** Pathological hallmarks observed in axons of MND is the ubiquitinated cytoplasmic inclusions containing the RNA processing proteins TDP43 and FUS. This indicates that protein aggregation may be involved in its pathogenesis similar to other neurodegenerative disorders. Other mechanism involved in pathogenesis may be oxidative neuronal damage, glutamate mediated excitotoxicity, mitochondrial dysfunction and impaired axonal transport.

Clinical presentation

- **Typical/spinal form** of ALS constitutes 2/3rd of cases. They present with simultaneous involvement of upper and lower motor neurons. Usually in one limb, spreading gradually. Often present with focal motor weakness of distal or proximal upper or lower limbs. The focal motor weakness spreads to contiguous muscles in the same region before involvement of another region. Then involves other limbs and trunk muscles.
- **Pseudoneurotic pattern:** Resembles neuropathy, i.e., involvement of muscles in the apparent distribution of a peripheral nerve. Fasciculations are present on wasted muscles.
- **Monomelic:** Involvement of one limb (as wasted leg syndrome, monomelic amyotrophy, Chopra's MND)
- **Pseudopolyneuritic:** Weakness in the both distal lower limbs.
- **Mills hemiplegic variant:** Weakness restricted to one half of the body.
- **Madras MND:** Associated sensorineural deafness, bifacial and bulbar weakness, bilateral optic atrophy in age <15 years.

Bulbar/Pseudobulbar Palsy (20%)

- Initially involves the lower cranial nerve nuclei and their supranuclear connections.
- Presents with weakness of respiratory group of muscles (e.g., dysarthria, dysphagia, nasal regurgitation of fluids and choking).
- About 10% present with bilateral upper limb weakness and wasting, flail arm of flail person in barrel syndrome.
- Head drop.
- Wasting and fasciculations of tongue seen almost in all patients **(Fig. 16.31)**.
- Cramps in the thighs, abdomen, back or even tongue.

- Nonmotor symptoms: Sleep disturbance, subtle cognitive dysfunction and mood changes.
- Rarely involved: Bladder, bowels, autonomic, extraocular movements and sensory.

Progressive Muscular Atrophy

- It presents as a pure lower motor neuron disease with symptoms of weakness, muscle wasting and fasciculation.
- Usually starts in one limb and gradually spreading to involve other adjacent spinal segments.

Primary Lateral Sclerosis (Rare 1–2%)

The least common form of MND. It involves upper motor neurons and presents with a slowly progressive tetraparesis and pseudobulbar palsy.

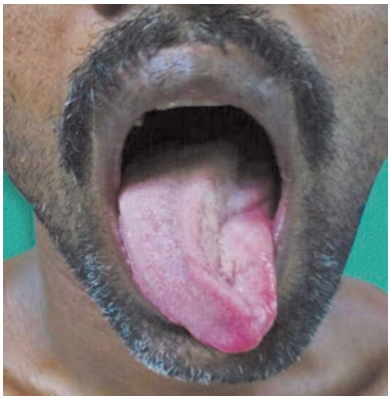

FIG. 16.31: Tongue wasting with atrophy.

Diagnosis of Amyotrophic Lateral Sclerosis

- No biological marker identified so far.
- Diagnosis is largely by series of clinical and neurological examinations.
- MRI: Coronal T2WI shows bilateral symmetrical hyperintensity along corticospinal tract (thin white arrows) forming a **"wine glass appearance"** or **"garland sign".**
- Myelogram of cervical spine (an X-ray analysis): Detects lesions in selected area of the spinal cord.
- Muscle and/or nerve biopsy.
- Electromyography and nerve conduction velocity (NCV) to measure muscle response to nervous stimulation.
    - **Split hand phenomenon:** In cases of severe changes in the thenar eminence and the relative sparing of hypothenar eminence, observed on the EMG study.

Differential Diagnosis of Amyotrophic Lateral Sclerosis

As amyotrophic lateral sclerosis in untreatable, all secondary causes should be excluded **(Box 16.41)**.

Box 16.41: Differential diagnosis of amyotrophic lateral sclerosis.

- **Other motor neuron diseases:** Primary lateral sclerosis (UMN only), progressive muscular atrophy (LMN only), progressive bulbar palsy
- **Structural lesions:** Cervical spondylosis, parasagittal/foramen magnum tumor, spinal cord AV malformation
- **Neuropathies:** Chronic inflammatory demyelinating polyneuropathy (CIDP)
- **Myopathies:** Polymyositis, inclusion body myositis
- **Neuromuscular junction disorder:** Myasthenia gravis
- **Neurodegenerative diseases:** Parkinson's, progressive supranuclear palsy, multiple sclerosis
- **Malignancy:** Primary/metastasis to CNS, motor neuron syndromes with multiple myeloma, lymphoma, lung, breast
- **Toxic exposure:** Alcohol, heavy metals
- **Endocrine:** Hyperthyroidism, hyperparathyroidism **Infectious:** HIV, CMV

Treatment

No treatment to arrest degeneration.

Drug therapy

- **Riluzole:** Dose 100 mg/day. It is a sodium channel blocker that reduces glutamate-induced excitotoxicity. Adverse drug reactions include asthenia, nausea, alterations in liver function tests, headache, abdominal pain, and tachycardia.
- **Trial drugs:** Edaravone, tamoxifen, sodium phenylbutyrate-taurursodiol, tofersen.
- **Spasticity**
    - Baclofen 5–10 mg twice daily to three times daily.
    - Tizanidine in the dose of 2–4 mg by mouth twice daily up to a total dose of 24 mg daily.
    - Memantine starting at 5 mg daily, increasing by 5 mg a week to a maximum of 20 mg twice a day.
    - Tetrazepam 50 mg at bedtime, increasing by 25 mg a day to a maximum dose of 150 mg taken two to three times a day.

Rehabilitation

- Foot drop splint
- Finger extension splint
- Respiratory support: Tracheostomy, positive pressure ventilation, cough assisted device.
- Bulbar involvement: Gastrostomy (for feeding), speech therapy.
- Physiotherapy, speech and occupational therapy.

Prognosis

Patient usually does not survive for >3 years, though rarely patients may survive for a decade or longer.

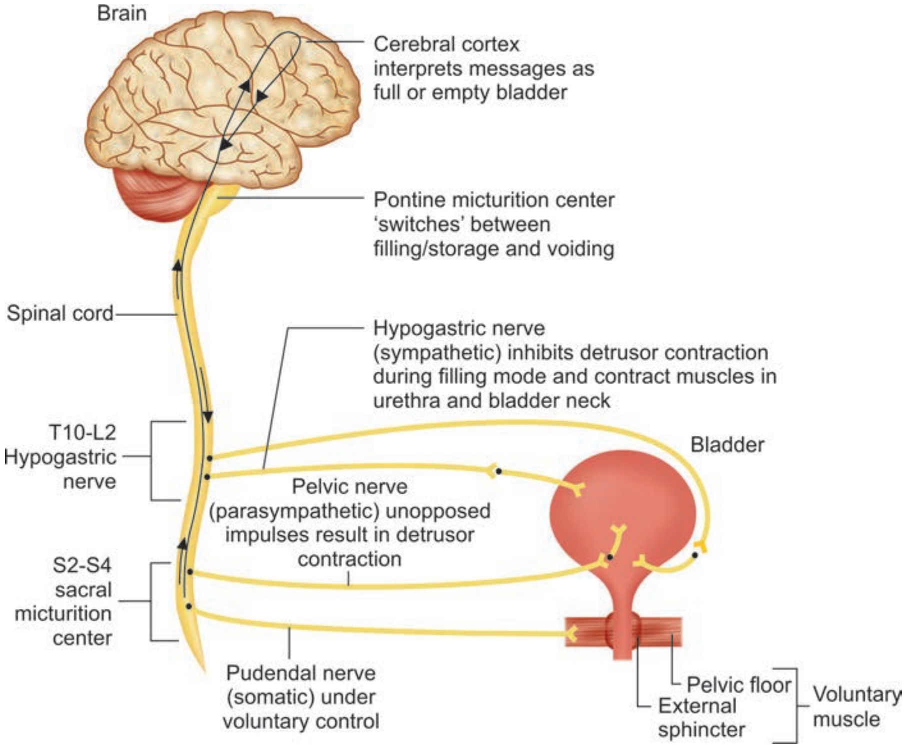
Neurogenic Bladder

Nerve Supply of Urinary Bladder

See **Figure 16.32.**

Q. Discuss the types of neurogenic bladder.

Dysfunction of urinary bladder due to neurological disorders is known as neurogenic bladder. Various causes of neurogenic bladder are listed in **Table 16.51.**



Brain
Cerebral cortex interprets messages as full or empty bladder
Pontine micturition center 'switches' between filling/storage and voiding
Spinal cord
Hypogastric nerve (sympathetic) inhibits detrusor contraction during filling mode and contract muscles in urethra and bladder neck
T10-L2 Hypogastric nerve
Bladder
Pelvic nerve (parasympathetic) unopposed impulses result in detrusor contraction
S2-S4 sacral micturition center
Pudendal nerve (somatic) under voluntary control
Pelvic floor
External sphincter
Voluntary muscle

FIG. 16.32: Nerve supply of urinary bladder.

TABLE 16.51: Various causes of neurogenic bladder.

Type	*Uninhibited bladder/ detrusor hyperreflexia*	*Automatic bladder/detrusor sphincter dyssynergia*	*Autonomous bladder/detrusor areflexia*	*Sensory atonic bladder*	*Motor atonic bladder*
Site of lesion	Suprapontine neurologic disorder, mostly frontal lobe	Upper motor neuron (UMN) disorder of the suprasacral spinal cord	Lower motor neuron (LMN) lesion at the sacral cord	LMN lesion—peripheral nerve	
Causes	Frontal tumors, parasagittal meningioma, ACA aneurysm, NPH	Spine cord trauma, compressive myelopathy, myelitis	Cauda equina syndrome, conus medullaris lesion, spinal shock	Diabetes mellitus, amyloidosis, tabes dorsalis	Lumbosacral meningomyelocele, tethered cord syndrome, lumbar canal stenosis
Bladder sensation	Preserved	Interrupted	Absent	Absent	Intact
Size of bladder	Normal	Small	Large	Large	Large
Ability to initiate voiding	Present	Absent	Absent	Present	Lost
Type of incontinence	Urge social disinhibition	Urge	Overflow	Overflow	Overflow
Residual urine	Nil	Small	Large amount	Large	Large
Anal sphincter tone	Normal	Normal	Lost	Normal	Lost
Perianal sensation	Normal	Normal	Absent	Absent	Preserved
Bulbocavernous/anal reflex	Normal	Normal	Absent	Absent	Preserved
Treatment	Anticholinergic medication	Self-intermittent catheterization	Continuous catheterization		

Transverse Myelitis

Q. Write a short note on transverse myelitis.

Transverse myelitis (TM) is an acute, usually monophasic, demyelinating inflammatory disorder affecting the spinal cord. It is characterized by acute or subacute motor, sensory and autonomic (bladder, bowel and sexual) spinal cord dysfunction.

- Myelitis refers to inflammation of the spinal cord and transverse signifies the involvement across one spinal cord level.
- Usually 1 or 2 spinal segments are affected with part or all of the cord area at that level involved.
- Varying degree of motor, sensory and autonomic disturbances are produced.

TABLE 16.52: Causes of transverse myelitis.

Disease	*Examples*
Bacterial infections	*Mycoplasma pneumoniae, Lyme borreliosis*, syphilis (tabes dorsalis), tuberculosis
Viral infections	Herpes simplex, herpes zoster, cytomegalovirus, Epstein–Barr virus, enteroviruses (poliomyelitis, coxsackie virus, echovirus), human T-cell, leukemia virus, human immunodeficiency virus, influenza, rabies
Postvaccination	Rabies, cowpox
Autoimmune diseases	SLE, Sjögren's syndrome, sarcoidosis, multiple sclerosis, neuromyelitis optica
Paraneoplastic syndromes	
Vascular	Thrombosis of spinal arteries, vasculitis secondary to heroin abuse, spinal arteriovenous malformation (AVM)

Causes of Transverse Myelitis (Table 16.52)

Q. Write a short note on clinical features of transverse myelitis.

It is usually thought to be postinfectious in origin and up to half of idiopathic cases will have a preceding respiratory or gastrointestinal illness. It is one of cause of a noncompressive spinal cord syndrome in which immune-mediated process may be responsible for neural injury of the spinal cord.

Clinical Features

- **Age:** It can occur at any age.
- **Symptoms develop rapidly** over several hours to several weeks which may worsen maximally within 24 hours.

Symptoms

- Lower limb weakness.
- Sensory: Sensation is diminished or absent below the level of involved spinal cord. Few patients experience tingling or numbness in the legs (subacute paraparesis). **Pain and temperature sensation are diminished**.
- **Bladder and bowel** dysfunction: It results in disturbed **sphincter control**.
- Lhermitte's sign: It is the radiation of paresthesias down the spine or limbs with neck flexion. It may be positive. It suggests intrinsic cervical spinal cord lesion.

Diagnosis

- First **exclude any mass-occupying lesion** compressing the spinal cord. Early surgical decompression results in complete recovery. MRI and CSF analysis may be useful in the diagnosis.
- **MRI:** MRI is sensitive and shows spinal cord swelling and edema with gadolinium enhancing lesions (single or multiple) at the affected level(s). MRI is also useful for excluding other treatable causes of spinal cord dysfunction (e.g., spinal cord compression).
- **CSF examination:** Shows cellular pleocytosis (usually monocytes/lymphocytes) often with polymorphs at the onset. Protein is slightly increased and IgG index is elevated. IgG index is a measure of intrathecal synthesis of immunoglobulin (Ig) and is calculated using the following formula: (CSF IgG/serum IgG)/(CSF albumin/serum albumin). Normal value is = 0.85 oligoclonal bands are usually absent.
- **Tests for exclusion of other treatable causes:** These include chest X-ray, tuberculin test, ESR, serologic tests (e.g., for mycoplasma, Lyme disease and HIV), vitamin B_{12} and folate levels, antinuclear antibodies (ANAs) and CSF and blood for VDRL (Venereal Diseases Research Laboratory) tests.

Treatment

- Treat the underlying cause or associated disorder. Otherwise it is mainly supportive.
- **High dose corticosteroids, intravenous immunoglobulin (IVIg) and plasmapheresis** are used in the treatment of **idiopathic cases**.
- **For severe, refractory cases:** Course of **azathioprine, methotrexate, mycophenolate, or oral cyclophosphamide**.

Outcome is variable and evolves over days. There may be no recovery. If present it may be **partial or complete** (often partial) and follows over weeks or months (1–3 months).

DISEASES OF THE PERIPHERAL NERVOUS SYSTEM

Introduction

Diseases of the PNS are common. They may affect the motor, sensory or autonomic components, either in isolation or combination. Cranial nerves III to XII share the same tissue characteristics as peripheral nerves and are prone to the same range of diseases.

Site of lesion: It may be (1) dorsal or ventral nerve root (radiculopathy), (2) brachial/lumbosacral nerve plexus (plexopathy) or (3) cranial nerves (except I and II), and other sensory, motor, autonomic or mixed nerves (neuropathy). Neuropathy is a pathological process affecting a peripheral nerve or nerves. It may be axonal, demyelinating or neuronopathy.

Classification

Peripheral nerve disorders can be broadly classified into three categories:

1. **Mononeuropathy simplex:** Signifies involvement of a single peripheral nerve [e.g., median nerve in carpal tunnel syndrome (CTS)].
2. **Mononeuropathy multiplex (now called multiple mononeuropathies):** Simultaneous or sequential several individual nerves involvement usually at random and noncontiguous (e.g., vasculitis, HIV leprosy).
3. **Polyneuropathy:** Function of numerous peripheral nerves is affected at the same time. This leads to a predominantly diffuse, distal and symmetric deficit usually commencing peripherally. It may be acute, chronic, static, progressive, relapsing or toward recovery. They are motor, sensory, sensorimotor and autonomic. They are classified into demyelinating and axonal types, depending on principal predominant pathological process. Typically, there is widespread loss of tendon reflexes with distal weakness and distal sensory loss.

Damage to peripheral nerve may affect the nerve cell body (axon) or the myelin sheath (Schwann cell), leading to axonal or demyelinating neuropathies.

Clinical Features

- **Motor nerve involvement:** It produces features of a lower motor neuron lesion.
- **Sensory nerve involvement:** It features depend on the type of sensory nerve involved; small fiber neuropathies are usually painful, present with paresthesias. Large fiber neuropathies cause sensory ataxia.
- **Autonomic involvement:** It may cause postural hypotension, disturbance of sweating, cardiac rhythm, and gastrointestinal, bladder and sexual functions. Commonly autonomic involvement complicates other neuropathies.

Diagnosis: By clinical pattern, nerve conduction/EMG, nerve biopsy, usually sural or radial, and detection of systemic or genetic disease.

Mononeuropathies

Focal involvement of a single nerve and implies a local process and may be due to direct trauma, compression or entrapment, leprosy, vascular lesions, neoplastic compression or infiltration, etc.

Peripheral Nerve Compression and Entrapment

- Nerves are susceptible to mechanical compression at a certain location (e.g., ulnar nerve at the elbow, common peroneal nerve at the head of the fibula, radial nerve at spiral groove of humerus, lateral cutaneous nerve of thigh at inguinal ligament, posterior tibial at tarsal tunnel). Focal compression or entrapment is the common cause of a mononeuropathy.
- Entrapment occurs in relatively tight anatomical passages (e.g., the carpal tunnel). At the site of compression, focal demyelination and mild degeneration of distal axonal develops.
- Predisposing causes for entrapment neuropathies include diabetes, excess alcohol or toxins, or genetic syndromes. These are recognized mainly by clinical features and diagnosis is confirmed by nerve conduction studies.
- Usually recover once the primary cause is removed, either by avoiding the precipitation of activity or by surgical decompression.

Carpal Tunnel Syndrome

Q. Write a short essay/note on carpal tunnel syndrome and its causes.

- **Common mononeuropathy** due to **entrapment of median nerve** at the wrist.
- Carpal tunnel syndrome is usually not associated with any underlying disease. However, it may be seen in: hypothyroidism, 3rd trimester of pregnancy, rheumatoid disease, amyloidosis in dialysis patients, and acromegaly.
- **Clinical features: Nocturnal pain, paresthesia/tingling on palmar aspect of hand and/or forearm and fingers**. It is usually poorly localized and not confined to the anatomical sensory territory of the nerve. At later stages, weakness and wasting of thenar muscles develop.
- **Tinel's sign** (elicited by tapping the flexor aspect of the wrist: this causes tingling and pain) and **Phalen's test** positive (the symptoms are reproduced on passive maximal flexion of wrist).
- **Treatment: Wrist splint at night** or a **local steroid injection** in mild cases. In pregnancy, CTS is self-limiting and subsides during postpartum. Definitive treatment is **surgical decompression** of the carpal tunnel.

Mononeuropathy Multiplex

- Simultaneous/sequential damage to multiple noncontiguous nerves (peripheral or cranial nerves).
- **Causes:** Ischemia caused by vasculitis (e.g., Churg–Strauss), microangiopathy in diabetes mellitus. Less common causes include HIV and hepatitis C infection, granulomatous, amyloidosis, leukemic, or neoplastic infiltration, neurofibromatosis, Hansen's disease (leprosy), toxins, paraneoplastic, and sarcoidosis.
- **Clinical features:** Symptoms will depend on the specific nerves involved. Several nerves may be affected sequentially or simultaneously, e.g., ulnar, median, radial and lateral popliteal nerves. When multifocal neuropathy is symmetrical, it is **difficult to distinguish** it from polyneuropathy.
- **Treatment:** Glucocorticoids, cytotoxic agents.

The causes of peripheral nerve disorders have been shown in **Table 16.53**.

TABLE 16.53: Causes of peripheral nerve disorders.

Causes of polyneuropathy	*Causes of mononeuropathy*	*Causes of mononeuritis multiplex*
Vitamin deficiencies: Thiamine, pyridoxine, vitamin B_{12}, vitamin E **Therapeutic drugs:** Amiodarone, antibiotics (dapsone, isoniazid, metronidazole, ethambutol), antiretroviral, chemotherapy (cisplatin, vincristine, thalidomide), phenytoin **Toxins:** Alcohol, nitrous oxide (recreational use) **Infections:** HIV, leprosy **Inflammatory:** Guillain–Barré syndrome, vasculitis (e.g., polyarteritis nodosa, granulomatosis with polyangiitis, SLE), paraneoplastic (antibody-mediated) **Systemic diseases:** Diabetes, renal failure **Malignancy:** Infiltration **Genetic conditions:** Charcot–Marie–Tooth disease (CMT), familial amyloid polyneuropathy, hereditary neuralgic amyotrophy **Others:** Paraproteinemias, amyloidosis	➢ **Acute:** Sustained pressure, e.g., tourniquet ➢ **Chronic:** Entrapment **Causes** (according to site of compression): ➢ Carpal tunnel—median nerve ➢ Cubital tunnel—ulnar nerve ➢ Spiral groove of humerus—radial nerve ➢ Inguinal ligament—lateral cutaneous of thigh (meralgia paresthetica) ➢ Neck of fibula—common peroneal nerve ➢ Flexor retinaculum (tarsal tunnel)—posterior tibial nerve **Entrapment neuropathies are commonly seen in:** ➢ Endocrinal (diabetes mellitus, myxedema, acromegaly) ➢ Amyloidosis ➢ Hereditary neuropathy susceptible to pressure palsy ➢ Pregnancy ➢ Arthritis (rheumatoid)	➢ Leprosy (most common) ➢ Diabetes mellitus ➢ Vasculitis ➢ Sarcoidosis ➢ Amyloidosis ➢ Malignancy ➢ Neurofibromatosis ➢ HIV infection ➢ Idiopathic multifocal motor neuropathy

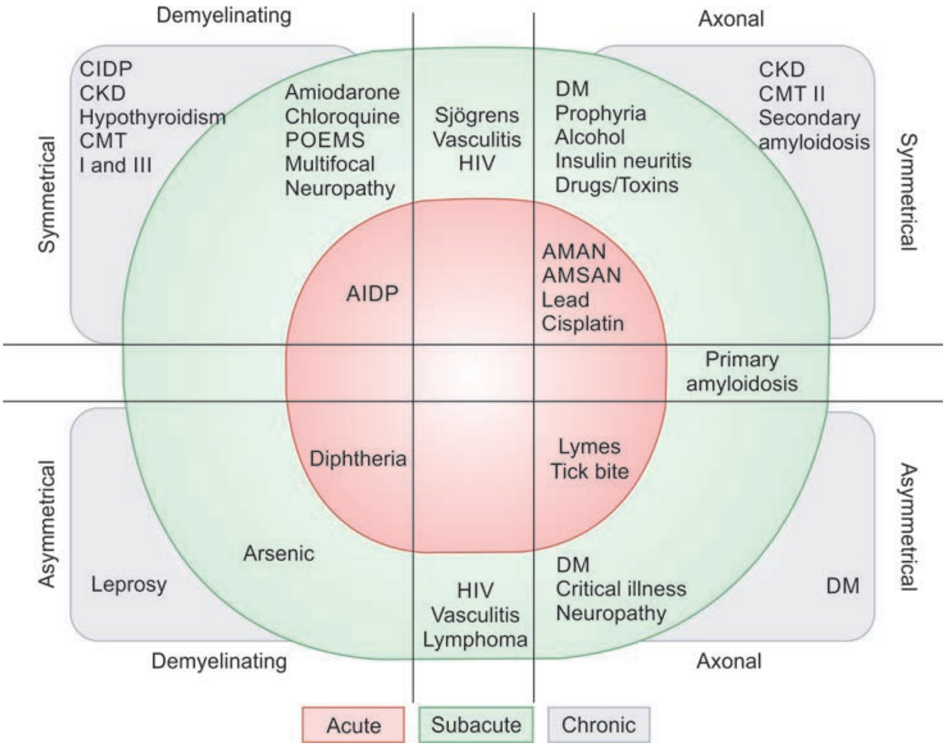
Polyneuropathies (Peripheral Neuropathy)

Q. Write a short essay/note on peripheral neuropathy and its causes/etiology.

Polyneuropathy is characterized by a "length dependent" pattern, occurring first in the longest peripheral nerves and affecting the distal lower limbs before the upper limbs. Sensory symptoms and signs occur in an ascending "glove and stocking" pattern. Types of peripheral neuropathy are presented in **Figure 16.33**.

Causes: Many diseases can produce polyneuropathy **(Table 16.53)**. However, the etiology is unknown in about 50% of cases.

Common causes of axonal and demyelinating chronic polyneuropathies are mentioned in **Table 16.54**.



Demyelinating
Axonal

FIG. 16.33: Types of polyneuropathy.

TABLE 16.54: Common causes of axonal and demyelinating chronic polyneuropathies.

Axonal		***Demyelinating***
➢ Diabetes mellitus ➢ Alcohol ➢ Uremia ➢ Cirrhosis ➢ Amyloid ➢ Myxedema, acromegaly ➢ Paraneoplastic ➢ Deficiency states: Thiamine, pyridoxine, vitamin B_{12}, vitamin E	➢ Hereditary ➢ Infection ➢ Idiopathic ➢ Drugs and toxins: Amiodarone, antibiotics (dapsone, isoniazid, metronidazole, ethambutol), antiretrovirals, chemotherapy (cisplatin, vincristine, thalidomide), phenytoin	➢ Chronic inflammatory demyelinating polyradiculoneuropathy ➢ Multifocal motor neuropathy ➢ Paraprotein-associated demyelinating neuropathy ➢ Charcot–Marie–Tooth disease type I and type X

Q. What are causes of peripheral nerve thickening?

Causes of peripheral nerve thickening **(Box 16.42)**.

Box 16.42: Causes of peripheral nerve thickening.

- Leprosy
- Chronic inflammatory demyelinating polyneuropathy (CIDP)
- Amyloidosis
- Charcot–Marie–Tooth disease
- Neurofibromatosis
- Diabetes
- Acromegaly
- Refsum disease
- Idiopathic
- Dejerine–Sottas disease
- Relapsing Guillain–Barré syndrome

Approach to Neuropathy (Table 16.55)

TABLE 16.55: Types and causes of neuropathy.

What is the onset and temporal evolution?

➢ Acute (days to 4 weeks)
➢ Subacute (4–8 weeks)
➢ Chronic (>8 weeks)

Contd...

Contd...

Acute onset	➢ Guillain–Barré syndrome ➢ Acute intermittent porphyria ➢ Critical illness polyneuropathy ➢ Thallium toxicity
Subacute onset	➢ Toxins or medications ➢ Nutritional deficiency ➢ Metabolic abnormality ➢ Paraneoplastic syndrome
Chronic	➢ Hereditary motor and sensory neuropathy (HMSN) ➢ Chronic inflammatory demyelinating polyneuropathy (CIDP) ➢ Chronic kidney disease (CKD)
Relapsing/remitting course	➢ Guillain–Barré syndrome ➢ CIDP ➢ HIV/AIDS ➢ Porphyria
What systems are involved? ***Motor (or) sensory (or) autonomic (or) mixed***	
Motor symptoms	
Negative symptoms	***Positive symptoms***
➢ Weakness ➢ Wasting ➢ Loss of dexterity In the early stage, weakness in peripheral neuropathy is distal; however, early proximal weakness is a feature of demyelinating neuropathy and porphyric neuropathy.	➢ Cramps ➢ Tremors ➢ Fasciculations ➢ Spasms
Neuropathic disorders that may have only motors symptoms at presentation ➢ Motor neuron disease ➢ Lead intoxication ➢ Acute porphyria ➢ Guillain–Barré syndrome ➢ Hereditary motor neuropathy ➢ CIDP ➢ Diphtheria ➢ Brachial neuritis ➢ Diabetic lumbosacral plexus neuropathy	
Sensory symptoms	
Negative symptoms	***Positive symptoms***
Numbness, loss of sensation in hands and feet	Burning, pain, walking on cotton wool, band-like sensation on feet or trunk, stumbling, tingling, pins and needles
Large fiber neuropathy: Neuropathy of signs/ataxic neuropathy There are few symptoms (numbness, ataxia) but lots of signs (loss of vibration, joint position sense, diminished reflexes, Romberg's sign positive) Examples: ➢ Sjogren's syndrome ➢ Vitamin B_{12} neuropathy ➢ Cisplatin ➢ Pyridoxine neurotoxicity ➢ Friedreich's ataxia	**Small fiber neuropathy:** Neuropathy of symptoms Lots of symptoms (pain—burning, shock-like, stabbing, prickling, shooting, lancinating, allodynia, tight band-like pressure insensitive to heat and cold) but very few signs (loss of pain, temperature) Examples: ➢ Diabetes ➢ Amyloidosis ➢ Fabry's disease ➢ HIV ➢ Tangier's disease ➢ Hereditary sensory and autonomic neuropathy ➢ Sjogren's syndrome ➢ Chronic idiopathic small fiber sensory neuropathy
Small and large fiber neuropathy—pansensory—global sensory loss Examples: ➢ Carcinomatous sensory neuropathy ➢ Hereditary sensory neuropathy ➢ Diabetic sensory neuropathy ➢ Vacor intoxication ➢ Xanthomatous neuropathy of primary biliary cirrhosis	

Contd...

Contd...

Peripheral neuropathies that are often associated with pain

- Cryptogenic sensory or sensorimotor neuropathy
- Diabetes mellitus
- Vasculitis
- Guillain–Barré syndrome
- Amyloidosis
- Toxic (arsenic, thallium)
- HIV related distal symmetrical polyneuropathy
- Fabry's disease

Autonomic symptoms

Inquire if the patient has fainting spells or orthostatic light headedness, sweating abnormalities or any bowel, bladder, or sexual dysfunction
Examples:

Acute	**Chronic**
➢ Pandysautonomia	➢ Amyloid
➢ Botulism	➢ Diabetes
➢ Porphyria	➢ Sjogren's
➢ Guillain–Barré syndrome	➢ HSN-1 and HSN-3
➢ Amiodarone	➢ Chagas
➢ Vincristine	➢ Paraneoplastic

PATTENS OF NEUROPATHY

- **Pattern 1:** Symmetric proximal and distal weakness with sensory loss
  - Inflammatory demyelinating polyneuropathy (GBS and CIDP)
- **Pattern 2:** Symmetric distal weakness with sensory loss
  - Metabolic disorders, hereditary toxins, drugs
- **Pattern 3:** Asymmetric distal weakness with sensory loss
  - Multiple nerves—vasculitis
  - Single nerves/regions—compressive mononeuropathy and radiculopathy
- **Pattern 4:** Asymmetric distal weakness without sensory loss
  - Motor neuron disease—with upper motor neuron findings
  - Multifocal motor neuropathy—without upper motor neuron findings
- **Pattern 5:** Asymmetric proximal and distal weakness with sensory loss
  - Polyradiculopathy or plexopathy due to diabetes mellitus
  - Meningeal carcinomatosis
- **Pattern 6:** Symmetric sensory loss without weakness
  - Cryptogenic sensory polyneuropathy (CSPN), metabolic (diabetes and others) drugs, toxins
- **Pattern 7:** Symmetric sensory loss and distal areflexia with upper motor neuron findings
  - Vitamin B_{12} deficiency, HIV, hepatic disease
- **Pattern 8:** A symmetric proprioceptive sensory loss without weakness
  - Sensory neuronopathy (ganglionopathy)
- **Pattern 9:** Autonomic symptoms and signs
  - Neuropathies associated with autonomic dysfunction
- **Pattern 10:** Syndrome of acute ascending motor paralysis
  - Guillain–Barré syndrome/acute idiopathic polyneuritis
  - Diphtheria
  - Porphyria
  - Triorthocresyl phosphate (TOCP) poisoning
  - Paraneoplastic
  - Postvaccinial
- **Pattern 11:** Syndrome of subacute sensory motor neuropathy
  - Deficiency—alcoholic beriberi, pellagra, vitamin B_{12}
  - Toxins—arsenic, lead (Pb), mercury (Hg)

- Drugs—nitrofurantoin, isoniazid (INH), dapsone, disulfiram, clioquinol
- Uremic
- Diabetes mellitus
- Polyarteritis nodosa (PAN), sarcoidosis

Approach to a Patient with Neuropathy (Box 16.43)

Investigation of Peripheral Neuropathy (Table 16.56)

Treatment

- Depends on the underlying cause.
- Symptomatic treatment (more details refer diabetic neuropathy).
- **Paresthesia:** Carbamazepine (300–1200 mg/day), amitriptyline (25–50 mg/day) or aspirin (350–1200 mg/day) pregabalin, gabapentin, duloxetine.
- **Weakness:** Physiotherapy.

Guillain–Barré Syndrome and other Immune-mediated Neuropathies

Q. Write a short essay/note on Guillain–Barré syndrome and diagnostic criteria for Guillain–Barré syndrome.

Guillain–Barré syndrome is a **heterogeneous group of immune-mediated conditions.**

Guillain–Barré syndrome is the most common acute, severe fulminant polyradiculopathy/polyneuropathy.

- Usually demyelinating or rarely axonal.
- Often postinfectious, postvaccinal basis
- Monophasic does not recur.

Subtypes of Guillain–Barré Syndrome (Table 16.57)

Q. What are the variants of Guillain–Barré syndrome?

Etiology

Antecedent causes

- Majority of patients (70%) have preceding acute, influenza-like illness or GI infection. Infections preceding GBS may be due to ***Campylobacter jejuni***, cytomegalovirus, EBV, herpes virus, CMV and ***Mycoplasma pneumoniae,*** or prior recent vaccination, e.g., swine flu, influenza, rabies (old types).
- Frequently develop in patients with lymphoma, HIV seropositive, and SLE.

Immunopathogenesis

- Guillain–Barré syndrome is **an acute-onset immune-mediated demyelinating neuropathy**. Autoimmune basis for AIDP (GBS) and other subtypes. Both cellular and humoral immune mechanism causes damage. Immune response to self-antigen, infection (mentioned above under "Antecedent causes"), or vaccine induce antibody responses. Molecular mimicry, i.e., sharing of homologous epitopes between microorganism liposaccharides and nerve gangliosides (e.g., GM1), misdirect the antibodies against host peripheral nerves.

Box 16.43: Approach to a patient with neuropathy.

Look for 6Ds

1. **D**istribution of the deficits
2. **D**uration
3. **D**eficits (which fibers are involved?)
4. **D**isease pathology (axonal or demyelinating or mixed)
5. **D**evelopmental or inherited neuropathy
6. **D**rug/toxin exposure

TABLE 16.56: Investigation of peripheral neuropathy.

Routine tests	*Special tests*
Blood ➢ Complete blood count and peripheral smear ➢ Erythrocyte sedimentation rate ➢ C-reactive protein **Biochemical tests** ➢ Fasting blood glucose, LDH ➢ Serum protein electrophoresis ➢ Vitamin B_{12}, folate ➢ Renal function tests, liver function tests **Serology** ANA, ANCA, HIV testing **Others** Chest X-ray, USG abdomen	➢ Nerve conduction studies ➢ Vitamins E and A ➢ Nerve biopsy ➢ CSF examination ➢ Serum ACE (angiotensin-converting enzyme) ➢ Serum amyloid ➢ Genetic testing

TABLE 16.57: Variants of Guillain–Barré syndrome.

Common variants	*Less common variants*
➢ Acute motor and sensory axonal neuropathy (AMSAN) ➢ Acute motor axonal neuropathy (AMAN) ➢ Miller Fisher syndrome (MFS) ➢ Pure motor variants ➢ Pure sensory variants ➢ Pure dysautonomia variant ➢ Pharyngeal-cervical-brachial variant ➢ Paraparetic variant (Ropper variant)	➢ Acral paresthesias with diminished reflexes in either arms or legs ➢ Facial diplegia or abducens palsies with distal paresthesias ➢ Isolated postinfectious ophthalmoplegia ➢ Bilateral foot drop with upper limb paresthesias ➢ Acute ataxia without ophthalmoplegia ➢ Bickerstaff's brainstem encephalitis (BBE)

- Antiganglioside antibodies mostly to GM1 common in GBS (20–50%) and anti-GQ1b IgG antibodies seen in Miller Fisher syndrome (MFS) (>90%).

Clinical Features

- Hallmark is an **acute/rapid onset of paralysis** (predominantly motor paralysis with/without sensory) **evolving over days or weeks** with **loss of deep tendon reflexes/jerk (areflexia)**.
- **Motor paralysis** predominant. Weakness beginning in the distal limbs (from lower to upper limbs) that rapidly ascends to affect proximal muscle function **("ascending paralysis")**. It is more marked in legs than arms and proximally than distally. Pain in the low back, neck, and shoulder, in 50% and is often occur early. The weakness progresses proximally over few days to a maximum of 4 weeks.
- **Sensory involvement is minimal** and may precede muscle weakness. It presents as distal paresthesia or loss of pain sensation.
- Facial and respiratory muscle develops in **20–30% of cases requiring ventilatory support**.
- **No fever or constitutional symptoms** at the onset of weakness.
- Bladder dysfunction in late and severe cases.
- Clinical worsening in 4 weeks reaching a plateau and no further progression.
- Autonomic disturbances common like fluctuation of BP, postural hypotension, cardiac dysrhythmias.
- Pain—common symptom—acute/deep aching pain in weak muscles. It is self-limited.
- Physical examination shows diffuse weakness with loss of reflexes.
- **Miller Fisher syndrome:** It presents with ophthalmoplegia, ataxia and areflexia. Often preceded by diarrhea due to *Campylobacter jejuni* infection. Bickerstaff's brainstem encephalitis (BBE) is characterized by alteration in consciousness, paradoxical hyperreflexia, ataxia, and ophthalmoparesis.

Asbury and Cornblath criteria for GBS are presented in **Box 16.44**.

Box 16.44: Asbury and Cornblath criteria for Guillain–Barré syndrome (GBS).

Required features
- Progressive weakness in both arms and legs
- Areflexia (or hyporeflexia)

Features supportive of diagnosis
- Progression of symptoms over days to 4 weeks
- Relative symmetry
- Mild sensory signs or symptoms
- Cranial nerve involvement, especially bilateral facial weakness
- Recovery beginning 2–4 weeks after progression ceases
- Autonomic dysfunction
- Absence of fever at onset
- Typical CSF (albuminocytologic dissociation)
- EMG/nerve conduction studies (characteristic signs of a demyelinating process in the peripheral nerves)

Features casting doubt on the diagnosis
- Asymmetrical weakness
- Persistent bladder and bowel dysfunction
- Bladder or bowel dysfunction at onset
- >50 mononuclear leukocytes/mm^3 or presence of polymorphonuclear leukocytes in CSF
- Distinct sensory level

Features that rule out the diagnosis
- Hexacarbon abuse
- Abnormal porphyrin metabolism
- Recent diphtheria infection
- Lead intoxication
- Other similar conditions: poliomyelitis, botulism, hysterical paralysis, toxic neuropathy

Investigations/Diagnosis

- **CSF findings:** Develop after 1 week of illness:
    - Raised protein (100–1,000 mg/dL), normal sugar, little or no pleocytosis. Cell count generally <10 cells/mm^3; rarely may be up to 50 cells/mm^3, but never above that. This is called as **albuminocytological dissociation**.
    - CSF pleocytosis (up to 50 cells) is common in patients who have GBS and concurrent HIV infection.
- **Electrodiagnostic study:** Nerve conduction studies:
    - In mild/early stage: Normal
    - In demyelination: Prolonged distal latencies, slow conduction, velocity, conduction block, prolonged F wave latencies. Absent H-reflex.
    - In primary axonal: Reduced amplitude of compound action potential without slow conduction.
- **Antibodies:**
    - Antibodies against GQ1b, a ganglioside component of nerve are found in about 25%, usually the motor axonal form.
    - Miller Fisher syndrome: Antibodies against GQ1b (ganglioside) have 90% sensitivity.

Differential Diagnosis

Exclusion of other causes of an acute neuromuscular paralysis. For example, poliomyelitis, botulism, diphtheria, localized spinal cord syndromes or myasthenia gravis, vasculitis, toxins (organophosphates, lead), diphtheria, porphyria, spinal cord or cauda equina syndrome.

Q. Write a short essay/note on principles of management of Guillain–Barré syndrome.

Treatment

- Early treatment, each day counts, >2 weeks of 1st motor symptoms immunotherapy not effective.
- Initiative with high dose IVIg/plasmapheresis/combination.
- **Intravenous immunoglobulin** administration has fewer side effects (0.4 g/kg daily infusion) for 5 days. GBS autoantibodies are neutralized by antibodies in IVIg. Patients should be screened for IgA deficiency because severe allergic reactions due to IgG antibodies may develop in patient with congenital IgA deficiency.
- **Plasma exchange:** 50 mL/kg, on 5 separate occasions over 1–2 weeks.
- Glucocorticoid no role.
- Full recovery in 55–69% by 1 year.
- **Worsening case:** Monitoring in intensive care unit (ICU)—blood pressure, cardiac, and nutrition. Maintenance of airway and breathing. Ventilatory support may be needed. **20-30-40 rule:** vital capacity <20 mL/kg, negative inspiratory pressure <–30 cm H_2O, maximum expiratory pressure <40 cm H_2O is an indication for intubation.
- **Supportive measures:** Deep vein thrombosis prophylaxis, tracheostomy, chest physiotherapy, skin care, bed sore, joint physiotherapy daily reassurance.

Plasma Exchange (Plasmapheresis)

Q. Write a short note on plasma exchange (PE) therapy.

Plasma exchange (also called plasmapheresis): Plasmapheresis involves the removal of small amounts of plasma (<15% of the patient's total blood volume). It can reduce the amount of abnormal protein in the blood. Indications for PE therapy are listed in **Box 16.45**.

Box 16.45: Indications for plasma exchange therapy.

- Glomerulonephritis—anti-GBM disease
- Guillain–Barré syndrome
- Myasthenia gravis
- Autoimmune encephalitis
- Prerenal transplant
- Systemic vasculitis not responding adequately to immunosuppressive therapy
- Thrombotic thrombocytopenic purpura

NEUROMUSCULAR JUNCTION DISORDERS

Myasthenia Gravis

Q. Discuss the etiology, clinical features, investigations, diagnosis, and management/treatment of myasthenia gravis (MG).

- Myasthenia gravis is an autoimmune neuromuscular junction disorder.
- Weakness and fatigue of skeletal (preferentially ocular, facial and bulbar) muscles.

Pathophysiology

See **Figure 16.34.**

Pathogenesis of Myasthenia Gravis

Myasthenia gravis is an autoimmune disease.

- **Antibodies:**
  - **Anti-AChR antibodies:** It is detected in about 80 to 85% of patients.
  - **Anti-MuSK antibodies:** A second group of autoantibodies against muscle-specific receptor tyrosine kinase (anti-MuSK) antibodies have been found in anti-AChR antibody negative (about 15–20%) patients.
- **Changes in thymus:** Thymus is abnormal in ~75% of patients with MG. In ~65% the thymus is "hyperplastic", with active germinal centers. In 10% of patients have thymic tumors (neoplastic). Muscle like cells (myoid cell) within thymus, bearing AChRs on their surface may serve as autoantigen and trigger immune response.

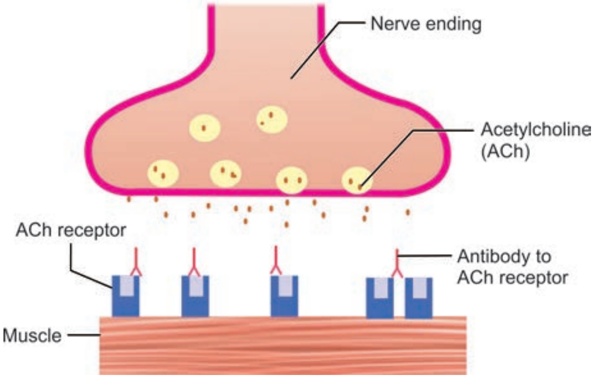

FIG. 16.34: Pathogenesis of myasthenia gravis. Antireceptor antibodies may inhibit/disturb the normal function of receptors. Autoantibodies to the acetylcholine receptor on skeletal muscle cells produce disease by blocking neuromuscular transmission and causing progressive muscle weakness.

Coexisting Autoimmune Diseases

See **Box 16.46**.

Box 16.46: Coexisting autoimmune diseases in myasthenia gravis.

- Hashimoto's thyroiditis/thyrotoxicosis (in 5–10%)
- Rheumatoid arthritis
- Pernicious anemia
- Scleroderma
- Lupus erythematosus

Clinical Features

- **Age and gender:** MG is common in women than in men (2:1). The disease presents with two peaks of incidence, below or above the age of 50, termed early-onset MG (EOMG) and late-onset MG (LOMG), respectively.
- **Cardinal feature: Fluctuating weakness** (**that worsens with exertion** and decrease with rest/sleep) **and fatigability of muscles**. Increase with exercise.
- **Muscle affected: Diplopia and ptosis** due to involvement of extraocular muscles. Show more focal muscle involvement (neck, shoulder, facial, jaw, respiratory, and bulbar muscles).
- **Respiratory weakness:** Respiratory muscles involvement may become so severe as to require respiratory assistance. Patient is said to be in due to diaphragmatic and intercostal muscle weakness. Aspiration may occur if the cough is ineffectual.
- **Ocular MG:** When weakness is exclusive to the eyelids and extraocular muscles, and **generalized MG** when weakness extends beyond these ocular muscles.
- No sensory signs or signs of involvement of the CNS.
- **Aggravating factors:** Exertion, hot climate, infection, emotion, pregnancy, menstruation, drugs (aminoglycoside phenytoin). A temporary increase in weakness may follow **vaccination, menstruation and exposure to extremes of temperature**.

Course: Variable, exacerbation and remission in early years. Remission is incomplete and temporary. Most cases have a protracted, lifelong course. Exacerbations are usually unpredictable and unprovoked.

Myasthenic crisis

- A **rapid and severe deterioration of myasthenia** is called **"myasthenic crisis"** can bring patient to the brink of respiratory failure and **quadriparesis** in hours.
- A respiratory infection or a sedative medication with NM (neuromuscular) block may be the reason.
- It can develop at any time after the diagnosis of myasthenia.
- Anticipate if patient is restless, anxious with diaphoresis and develops tremor.
- **Require respiratory support**.

Diagnosis

- Diagnosis is based on the basis of **clinical history, physical findings and two-positive tests** (demonstration of autoantibodies and electrophysiological studies).
- **Serological tests:** Antibodies against AChR or MuSK.
- **Pharmacological tests:**
  - **Anticholinesterase test:** Drugs inhibiting AChE allow ACh to interact repeatedly with limited number of AChRs producing strength improvement in myasthenic muscles.
  - **Edrophonium test (Tensilon test):** Edrophonium is a rapidly acting acetylcholinesterase inhibitor. Onset of action is rapid (30 seconds) and lasts for short duration (5 minutes). It reverses of muscular weakness dramatically in myasthenia. Test dose (2 mg IV) is given to check for reactions. If there is definite improvement drop further test. If negative further 8 mg IV is given. When the test is positive, it produces substantial improvement in weakness, ptosis, diplopia, nasal voice, etc., within 30 seconds and lasts for up to 5 minutes. Positive test is highly suggestive of MG and the sensitivity of the test is 80%. Adverse effect include nausea, diarrhea, salivation, bradycardia, syncope, abdominal cramps, fasciculation (treated with atropine—0.6 mg IV) bronchospasm and syncope.
  - **Neostigmine/Prostigmine test:** 15 mg oral neostigmine, long acting and better evaluation.
- **Ice on eyes/ice pack test (Fig. 16.35):** Apply an ice pack on eye for 3 to 5 minutes. The response is positive when there is increase in at least 2 mm of the palpebral fissure from before to after the test.

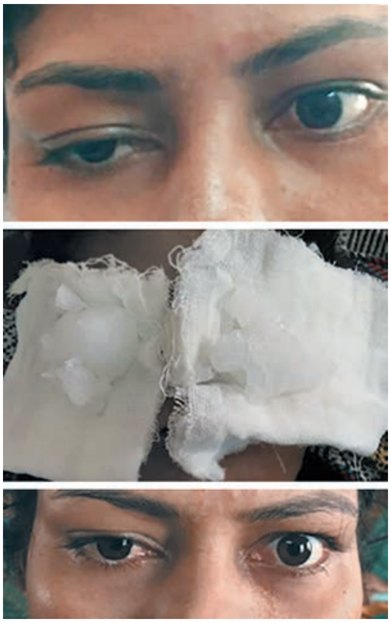

FIG. 16.35: Ice pack test.

- **Electrodiagnostic:**
  - **Repeated nerve stimulation (RNS) test:** Electric shock at 2–3 second given to appropriate nerve and corresponding muscle action potential measured. In normal individuals the amplitude of the evoked muscle action potentials does not change at these rates of stimulation. However, in myasthenic patients there is a rapid reduction of >10–15% in the amplitude of the evoked responses during repetitive stimulation.
  - **Single fiber electromyogram:** Most (95%) sensitive.
- **Other tests:**
  - CT, MRI, and X-ray—to exclude thymoma.
  - CBC, ESR, RA factor, thyroid function test.
  - Pulmonary function test, fasting blood sugar, Mantoux test, ANA, etc., to exclude other diseases.
  - Screening for associated autoimmune disorders.

Lambert–Eaton myasthenic syndrome (LEMS) differs from MG in that in LEMS antibodies are against presynaptic calcium channels, deep tendon reflexes are absent and autonomic dysfunction in present and the weakness improves with activity in LEMS. It is most commonly associated with small cell carcinoma of lung and the treatment is with aminopyridines.

Q. **Write a short note on drugs used in myasthenia gravis.**

Treatment

Goals: To increase the activity of acetylcholine on the remaining receptors at the NMJ. Stop the antibody mediated damage at the NMJ.

1. **Oral anticholinesterases:** Help weakness but do not change the natural history of myasthenia.
   - **Pyridostigmine:** Prolongs acetylcholine action by inhibiting cholinesterase. Onset of action is within 15–30 minutes and lasts for 3–4 hours. Dose 30–60 mg/3–4 times daily. Cholinergic crisis characterized by pallor, perspiration, pupillary constriction, paralysis, fasciculation and excessive salivation can be seen with drug over dosage. Muscarinic effects (e.g., colic and diarrhea) are treated with oral atropine/propantheline (antimuscarinic).
2. **Thymectomy**
   - **Indications:** It is an expert surgical procedure that should be carried out in (1) all patients with generalized MG between the ages of puberty and at least 55 years. (2) It may be required for thymoma to prevent spread and treat MG.
   - **Advantages:** Long-term benefit, improves prognosis, negligible medication.
3. **Immunosuppression**
   - Effective in all. Choice is guided by benefit, risk and urgency. These are used in patients who do not respond to pyridostigmine or who develop relapse on treatment.
   - For immediate: IVIg or plasmapheresis.
   - For intermediate: Glucocorticoids, cyclosporine, tacrolimus for 1–3 months.
   - For long-term: Azathioprine, mycophenolate mofetil (less commonly used) for months/years.
   - For refractory: High dose of cyclophosphamide.

The differences between myasthenic crisis and cholinergic crisis are presented in **Table 16.58**.

Treatment of myasthenic crisis

- Exacerbation of weakness due to diaphragm and intercostal involvement.
- Treat in ICU setup.
- Cause: Infection (most common), cholinergic crisis due to excess anticholinesterase dose.
- Respiratory assistance (preferably noninvasive, using BIPAP).
- Pulmonary physiotherapy.
- Plasmapheresis or IVIg.
- Stop anticholinesterase if using.

TABLE 16.58: Differences between myasthenic crisis and cholinergic crisis.

Myasthenic crisis	*Cholinergic crisis*
➢ Due to disease worsening	➢ Due to drug overdose
➢ Respiratory distress	➢ Abdominal cramps
➢ Increased pulse and blood pressure	➢ Diarrhea
	➢ Nausea and vomiting
➢ Poor cough	➢ Excessive secretions
➢ Mydriasis	➢ Miosis
➢ Dysphagia	➢ Fasciculations
➢ Weakness	➢ Weakness
➢ Improve with edrophonium	➢ Worsens with edrophonium
➢ Treatment: Ventilatory support plus neostigmine	➢ Treatment: Ventilatory support plus atropine

DISEASES OF MUSCLE

- Muscle disease is rare and may be hereditary or acquired.
- Hereditary muscle diseases include the muscular dystrophies, muscle channelopathies, metabolic myopathies (including mitochondrial diseases) and congenital myopathies.
- Skeletal muscle disease or myopathies are disorders with structural changes or functional impairment of muscle.

Muscular Dystrophies

Muscular dystrophies (hereditary myopathies) refer to a group of inherited myopathies/disorders characterized by progressive muscle weakness and wasting (due to destruction of muscle) and may be associated with cardiac and/or respiratory involvement.

Q. Write a short note on muscular dystrophies or hereditary myopathies.

Muscular dystrophy is subdivided by their mode of inheritance, age at onset, distribution of involved muscles, rate of progression, and prognosis **(Table 16.59)**.

Duchenne Muscular Dystrophy

Q. Write a short essay on Duchenne muscular dystrophy.

- Most common form of muscular dystrophy.
- Caused by a mutation of the gene responsible for producing dystrophin.
- Shows X-linked recessive inheritance and affects predominantly males.
- Duchenne dystrophy is present at birth, but the disorder usually becomes apparent between ages 3 and 5, by age 12, most patients are wheelchair dependent.
- Muscle selectively involved in order of appearance of weakness is iliopsoas, quadriceps, gluteus-pretibial muscles, muscles of pectoral girdle, muscles of leg and forearm (at the end).
- **Clinical features:** Use of **Gower's maneuver** while getting up for the floor, toe walking due to foot drop with associated lordotic posture and pseudohypertrophy of the calves. Cardiomyopathy [dilated cardiomyopathy (DCM)] and mental impairment are associated features. But CHF is uncommon. Mental retardation is seen.
- **Investigations**
  - Creatine phosphokinase (CPK) levels are invariably elevated to between 20 and 100 times normal.
  - Electromyography: Features typical of myopathy.
  - Muscle biopsy: Definitive diagnosis can be established on the basis of dystrophin deficiency I in biopsied muscle tissue.
  - Gold standard: It is genetic testing.

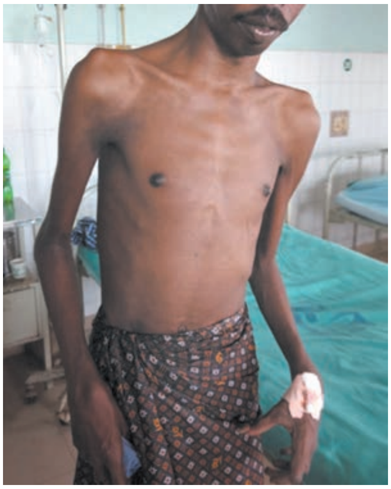

FIG. 16.36: Facioscapulohumeral dystrophy.

TABLE 16.59: Various subtypes and its features of muscular dystrophies.

Type and mode of inheritance	*Defective gene/protein*	*Onset age*	*Clinical features*
Duchenne's-XR	Dystrophin	Before 5 years	Progressive weakness of girdle muscles unable to walk after age 12, progressive kyphoscoliosis, respiratory failure in the 2nd and 3rd decades
Becker's-XR	Dystrophin	Early childhood to adult	Progressive weakness of girdle muscles, able to walk after age 15, respiratory failure may develop by 4th decade
Limb-girdle-AD/AR	Several	Early childhood to early adult	Slow progressive weakness of shoulder and hip girdle muscles
Emery–Dreifuss-XR/AD	Emerin/Lamins	Childhood to adult	Elbow contractures, humeral and peroneal weakness
Dystrophia myotonica (DM1-DM2)-AD DM1-Steinert disease DM2-Ricker syndrome	DMI: Expansion CTG repeat DM2: Expansion CCTG repeat	Childhood to adult, may be infancy if mother is affected (DM1 only)	Slowly progressive weakness facial muscles (levator palpebrae superficialis, temporalis), sternocleidomastoids (dropped neck), distal muscles of the forearm, hand intrinsic muscles, and ankle dorsiflexors (foot drop). Weakness in the hip girdle is often the presenting feature of DM2
Facioscapulohumeral-AD **(Fig. 16.36)**		Childhood to adult	Slowly progressive weakness of face, shoulder girdle, and foot dorsiflexion
Oculopharyngeal-AD	Expansion poly-A RNA-binding protein	5th to 6th decade	Slowly progressive weakness of extraocular, pharyngeal, and limb muscles

Becker Muscular Dystrophy

- X-linked disorder, results from defects of the same gene responsible for Duchenne dystrophy.
- Pattern of muscle wasting closely resembles that seen in Duchenne.
- It is a less severe form of disease and much less frequent than Duchenne.
- **Clinical features:** Becker patients ambulate beyond age 15, while patients with Duchenne dystrophy are typically in a wheelchair by the age of 12; allowing for a clinical distinction between Becker and Duchenne dystrophy. Cardiac involvement occurs in Becker dystrophy and may result in heart failure. Mental impairment is uncommon.
- **Investigations:** Serum CK measurement, EMG and muscle biopsy closely resemble those in Duchenne dystrophy.

Limb-Girdle Muscular Dystrophy

- Most are progressive and affect primarily the pelvic and shoulder girdle muscles. Inheritances can AR or AD and it is due to defect of sarcoglycan.
- **Clinical features:** Respiratory insufficiency from diaphragm weakness may occur. In some patients, cardiac involvement results in CHF or arrhythmias, occasional patients present with a cardiomyopathy. Intellectual function remains normal.
- **Investigations:** An elevated serum CK level, myopathic EMG findings, and muscle biopsy features indicative of myopathy.

Myotonic Dystrophy

- It is an autosomal dominant disorder and is the most common adult muscular dystrophy.
- **Clinical features:** Frontal baldness, cataracts (Christmas tree cataract), mental impairment, insulin resistance and gonadal atrophy. Hatchet like face, swan neck deformity is seen. Involvement of distal more than proximal, facial muscles and handgrip myotonia are pathognomonic features. Cardiac disturbances occur in most patients with myotonic dystrophy. Disturbances in conduction system are common. Complete heart block and sudden death may occur. Mitral valve prolapse also occurs commonly in myotonic dystrophy patients. Myotonia may improve with phenytoin, mexiletine, and quinidine.

Box 16.47: Causes of endocrine myopathies.

- **Thyroid disorders:** Hypothyroidism, hyperthyroidism
- **Parathyroid disorders:** Hyperparathyroidism, hypoparathyroid—overt myopathy
- **Adrenal disorders:** Glucocorticoid myopathy (endogenous/exogenous) most common, Cushingoid, adrenal insufficiency, primary hyperaldosteronism (Conn's disease)
- **Vitamin deficiency:** Vitamin E, vitamin D

Box 16.48: Causes of high creatinine phosphokinase.

- Brain injury or stroke
- Convulsions
- Delirium tremens
- Dermatomyositis or polymyositis
- Myocarditis
- Muscular dystrophies
- Myopathy
- Rhabdomyolysis
- Pulmonary and myocardial infarction
- Electric shock

Endocrine Myopathies

Causes of endocrine myopathies are listed in **Box 16.47**.

Q. Write a short note on causes of endocrine myopathies.

Causes of high creatinine phosphokinase **(Box 16.48)**.

Q. List the causes of high creatinine phosphokinase.

DISORDERS OF CEREBELLAR FUNCTION

- Cerebellum is an infratentorial structure in the posterior cranial fossa, attached to the brainstem by the superior, middle and inferior peduncles. The cerebellum is made up of two hemispheres separated by a midline vermis. There are three lobes—anterior, posterior, and flocculonodular lobe.
- Midline lesions can produce severe gait and truncal ataxia.
- Cerebellar hemisphere lesions can produce classic ipsilateral limb ataxia (intention tremor, past pointing, and mild hypotonia).

Ataxia

Ataxia may be the result of cerebellar lesion or due to a combination of cerebellar and extracerebellar lesions.

Classification of Ataxia

See **Box 16.49.**

Box 16.49: Classification of ataxia.

Acquired or sporadic ataxias

- **Vascular:** Stroke (infarction, hemorrhage), AV malformations
- **Infectious/postinfectious diseases:** Acute cerebellitis, cerebellar abscess, postinfectious encephalomyelitis, HIV, chickenpox
- **Toxin-induced ataxias:** Alcohol, drugs (antiepileptic agents, lithium, antineoplastics, cyclosporine, metronidazole), heavy metals (mercury), 5-fluorouracil, cytosine arabinoside
- **Structural and neoplastic causes:** Gliomas, ependymoma, cerebellar tumor, meningioma, metastatic disease
- **Immune-mediated:** Multiple sclerosis, cerebellar ataxia with anti-glutamic acid decarboxylase (GAD) antibodies, paraneoplastic syndrome (small cell lung cancer, breast or ovarian cancer, and lymphoma), gluten ataxia
- **Deficiency:** Hypothyroidism, vitamin B_1, vitamin B_{12}, and vitamin E

Genetic causes

- Autosomal recessive: Friedreich's ataxia
- Autosomal dominant: Spinocerebellar ataxia

Symmetrical Cerebellar Ataxias

See **Table 16.60.**

Asymmetrical Cerebellar Ataxias

See **Table 16.61.**

Treatable Causes of Ataxia

See **Box 16.50**.

Clinical Features of Cerebellar Lesions

Q. Write a short note on cerebellar signs.

Cerebellar Ataxia

Q. Write a short note on cerebellar ataxia.

Lesions of the midline vermis of the cerebellum cause truncal ataxia, while lesions of the cerebellar hemispheres cause limb ataxia of the ipsilateral side.

1. **Gait ataxia**
    - Patients will tend to stand with feet well apart and are often frightened to stand.
    - Patients tend to reel to the side unilateral lesion or from side to side if central or bilateral (drunken gait) (even if supported).
    - Walking along a line of the floor (tandem gait) demonstrates minor degrees of gait ataxia.
    - Instability may increase if eyes are closed but patients do not fall. This is not a true positive Romberg's test (true positive Romberg's test is present when there is impaired joint proprioception/posterior column involvement is known as sensory ataxia).

TABLE 16.60: Types of symmetrical cerebellar ataxias.

Acute	*Subacute*	*Chronic*
➢ Drugs: Phenytoin, phenobarbitone, lithium, chemotherapeutic agents ➢ Alcohol ➢ Infectious: Acute viral cerebellitis, postinfectious ➢ Toxins: Toluene, glue, gasoline, methyl mercury	➢ Alcohol or nutritional (B_1, B_{12}) ➢ Paraneoplastic ➢ Antigliadin or anti-GAD antibody ➢ Prion diseases	➢ Multiple system atrophy, cerebellar type C (MSA-C) ➢ Hypothyroidism ➢ Phenytoin toxicity

TABLE 16.61: Types of asymmetrical cerebellar ataxias.

Acute	*Subacute*	*Chronic*
➢ Vascular: Cerebellar infarction or hemorrhage, subdural hematoma ➢ Infectious: Abscess	➢ Neoplastic: Glioma, metastases, lymphoma ➢ Demyelination: MS ➢ HIV-related: Progressive multifocal leukoencephalopathy	Congenital lesions: Arnold–Chiari malformation, Dandy–Walker syndrome

Box 16.50: Treatable causes of ataxia.

- Hypothyroidism
- Ataxia with vitamin E deficiency (AVED)
- Vitamin B_{12} deficiency
- Wilson's disease
- Ataxia with anti-gliadin antibodies and gluten sensitive enteropathy
- Ataxia due to malabsorption syndromes
- Lyme disease
- Mitochondrial encephalomyopathies, aminoacidopathies, leukodystrophies, and urea cycle abnormalities

Q. Write a short note on Romberg's sign/test

- **Romberg's test is a test for sensory ataxia.**
- **Romberg's test/sign:** Patient stands upright with the feet together (touching each other) and eyes closed. When there is proprioceptive or vestibular deficit, balance is impaired only when eyes are closed, and the patient may fall if not caught. Minimal lesions can be demonstrated by asking the patient to stand on his toes with eyes closed.
- **Principle of Romberg's test:** It is based on the principle that an individual requires at least two of the three following senses to maintain balance while standing:
    - Proprioception (the ability to know one's body in space)
    - Vestibular function (the ability to know one's head position in space); and
    - Vision [which can be used to monitor (and adjust for) changes in body position].

2. **Truncal ataxia**
    - Patients cannot sit or stand unsupported and tend to fall backward.
    - It is caused by a midline cerebellar lesion, or may be a feature of post-chickenpox cerebellar syndrome.
    - Truncal tremor may be evident—constant jerking of trunk and head (titubation).
    - Lesions of the cerebellar hemisphere cause ipsilateral limb signs.
    - The outstretched arm tends to be held hyper-pronated at rest and at a slightly higher level than unaffected side **(Riddoch's sign)** and rebounds upward if gently pressed downward and then suddenly released by the examiner.
    - Finger-nose and heel-knee-shin tests will demonstrate even mild limb ataxia, with terminal intention tremor and dysmetria (past pointing).
    - Limb rebound can be demonstrated by gently pushing down on outstretched arms and then suddenly releasing, causing the arm on the affected side suddenly to fly upward.
    - Pendular knee jerks and hypotonia present.

3. **Other signs** produced by cerebellar lesions/diseases
    - **Cerebellar dysarthria:** Spluttering staccato speech. Scanning dysarthria is a jerky and explosive speech with separated syllables may be demonstrated by asking the patient to repeat baby hippopotamus!
    - **Dyssynergia:** It is difficulty in carrying out complex movements. This results in breaking of an act into its components.
    - **Macrographia:** Writing may be larger than normal (contrast with micrographia of Parkinson's disease).
    - **Rapid alternating movements:** Inaccuracies in rapidly repeated movements (dysdiadochokinesia). This is demonstrated by getting the patient to tap back of their own hand repeatedly with the other hand, or to tap their foot on the floor.
    - **Tremor:** Unilateral or bilateral intention tremor, or a truncal tremor.
    - **Nystagmus:** Coarse nystagmus, worse, on looking to the side of lesion with fast component toward the affected side.
    - **Pendular knee jerk:** The reflexes are less brisk and slower in rise and fall. This produces pendular jerk at the knee. It produces three on more swings at the knee when the knee reflex is elicited with patient in sitting posture and the legs hanging from bedside.
    - **Nausea and vomiting:** Sudden vomiting (without warning) after a positional change, without preceding nausea, is suggestive of a posterior fossa lesion.

Mnemonic for cerebellar signs **(Box 16.51)**.

Box 16.51: Mnemonic for cerebellar signs—DANISH.

- **D**ysdiadochokinesia and Dysmetria
- **A**taxia
- **N**ystagmus
- **I**ntention tremor
- **S**lurred speech
- **H**ypotonia

Hereditary Cerebellar Ataxia—Friedreich's Ataxia

- Most common form of inherited ataxia. Most common form degenerative ataxia caused by unstable trinucleotide GAA expansion in chromosome located on 9q. The protein involved is frataxin.
- It affects spinal cord—dorsal column, spinocerebellar tract, and pyramidal tract. There is also loss of dorsal root ganglion cells with depletion of large myelinated fibers in peripheral nerves.
- Age of onset usually between 8 and 16 years.

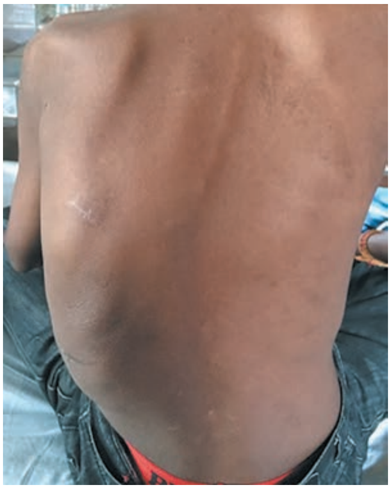

FIG. 16.37: Patient with scoliosis due to Friedreich's ataxia.

Clinical Features

- Progressive ataxia of gait (due to spinocerebellar tract involvement).
- Lower limb areflexia and later generalized areflexia.
- Leg weakness and extensor plantar responses (due to pyramidal tract involvement).
- Reduced vibration and joint position sense in lower limbs. It is due to involvement of dorsal column.
- Sensory axonal neuropathy detected on nerve conduction test.
- **Other features:** Dysarthria, scoliosis **(Fig. 16.37)**, nystagmus, optic atrophy, deafness, diabetes, pes cavus and cardiomyopathy.

Causes of extensor plantar response with absent ankle jerk are listed in **Box 16.52**.

Box 16.52: Causes of extensor plantar response with absent ankle jerk.

- Friedreich's ataxia
- Motor neuron disease (ALS)
- Taboparesis in neurosyphilis
- HIV myeloneuropathy
- Subacute combined degeneration of cord (vitamin B_{12} deficiency)
- Hypocupremic myelopathy
- Conus-cauda lesion

Investigations

- **Nerve conduction study (NCS):** Normal conduction velocity but small or absent sensory nerve action potential (SNAP)
- CT and MRI normal cerebellar anatomy, cervical atrophy.
- DNA polymerase reaction to detect GAA expansion.

Treatment

No definite treatment, physiotherapy and occupational therapy, spasticity is treated with baclofen, orthopedic advice and surgery.

Spinocerebellar Ataxia (Late-Onset Hereditary Ataxia)

Q. Write a short note on the clinical features of spinocerebellar ataxias.

- Spinocerebellar ataxia (autosomal dominant cerebellar ataxia/ADCA) is an autosomal dominant disease that presents with slowly progressive cerebellar symptoms. Sometimes with associated optic atrophy, ophthalmoplegia, pyramidal and extrapyramidal structure.
- MRI mostly shows olivopontocerebellar atrophy.

Sensory ataxia

It is due to severe sensory neuropathy, ganglionopathy or lesions of the posterior column of the spinal cord, e.g., Sjogren's syndrome, cisplatin, CIDP, paraneoplastic disorders, SACD, tabes dorsalis, Miller Fischer syndrome, celiac disease.

- Ataxia more at night or while walking through narrow passages (coffee plantations).
- A history of falling into the sink or imbalance when splashing water on the face (wash-basin sign), passing a towel over the face or pulling a shirt over the head should also be sought.
- Pseudoathetosis—"piano-playing" movements—when the patient has his arms outstretched and eyes closed, the affected arm will wander from its original position.
- Vibration and position sense are usually lost together.
- Positive Romberg's test is a hallmark of sensory ataxia.

Vestibular ataxia is due to lesion of vestibular pathways resulting in impairment and imbalance of vestibular inputs, e.g., vestibular, neuronitis, streptomycin toxicity.

- Vertigo and associated tinnitus and hearing loss
- Direction of the nystagmus in away from the lesion.

Optic ataxia was first described in a man with lesions of the posterior parietal lobe on both sides of the brain, later became known as **Balint's syndrome**.

- Among the symptoms that characterize the syndrome are a restriction of visual attention to single objects and a paucity of spontaneous eye movements.
- Patients have difficulty completing visually guided reaching tasks in the absence of other sensory cues.

Frontal lobe ataxia (Bruns ataxia) is due to involvement of subcortical small vessels, Binswanger's disease, multi-infarct state or NPH.

- The gait may appear to be a combination of awkward, magnetic (stuck to the floor), cautious, slow, and shuffling. This is also known as a frontal gait disorder, referring to the frontal lobe conditions which often cause gait apraxia.

The characteristic features of different types of ataxia have been shown in **Table 16.62**.

TABLE 16.62: Characteristic features of different types of ataxia.

Type of ataxia	*Cerebellar*	*Sensory*	*Frontal*
Stance and support	Wide based	Narrow based; looking down	Wide based
Velocity	Variable	Slow	Very slow
Stride	Irregular, lurching	Regular with path deviation	Short, shuffling
Romberg's	±	Unsteady; patient falls	±
Heel-Shin test	Abnormal	±	Normal
Initiation	Normal	Normal	Hesitant
Postural instability	+	+++	+++++
Falls	Late event	Frequent	Frequent
Turns	Unsteady	±	Multistepped; hesitant

MOVEMENT DISORDERS

Types of Movements

Q. IM19.2 Classify movement disorders of the brain-based on distribution, rhythm, repetition, exacerbating and relieving factors.

- **Akathisia:** A subjective feeling of inner restlessness that is relieved by movements (e.g., crossing and uncrossing legs, rocking back and forth and pacing).
- **Asterixis:** Sudden periods of cessation of muscle contraction best seen when the patient's arms are extended in front. It is a negative myoclonus.
- **Athetosis:** Slow, sinuous, writhing movements, usually of the distal parts of the limbs.
- **Ballismus:** Wild flinging, movements that represent large amplitude proximal choreiform movements. Ballismus is often unilateral (hemiballismus).
- **Chorea:** Semipurposeful flowing movements that flit from one part of the body to another in a continuous and random pattern. Chorea can be defined as involuntary movements that are abrupt, unpredictable and nonrhythmic, resulting from a continuous random flow of muscle contractions.
- **Dyskinesia:** A general term for any excessive movement. The term dyskinesia is often used as an abbreviation for "tardive dyskinesia" (repetitive oral movements often seen in patients taking certain psychiatric medications).
- **Dystonia:** Twisting movements that are often sustained for variable periods of time with a directional preponderance resulting in posturing.

Algorithmic approach to movement disorders is given in **Flowchart 16.8**.

FLOWCHART 16.8: Algorithmic approach to movement disorders.

Dystonia
No
Athetosis

Q. Write a short note on myoclonus and its causes.

- **Myoclonus:** Myoclonic movements are sudden, brief, shock-like involuntary movements, which are usually positive (caused by muscle contraction), but can sometimes be negative [due to brief loss or inhibition of muscular tonus, as in asterixis—for example, when caused by hepatic encephalopathy (liver flap) or in uremic encephalopathy] **(Table 16.63)**.
- **Tics:** Tics are sudden and jerky movements, but in this case the keyword for recognition is the "stereotyped" character of the recurrent movements. Repetitive, stereotypic movements or sounds that are suppressible and that relieve a feeling of inner tension.
- **Tremor:** Regular, oscillatory movements that may be present at rest or with action. Tremor is characterized by involuntary, rhythmic and sinusoidal alternating movements of one or more body parts.

TABLE 16.63: Causes of some important movement disorders.

Name of disorder	***Causes***	***Treatment***
Asterixis	➢ Hepatic encephalopathy ➢ Uremic encephalopathy ➢ Carbon dioxide narcosis	Haloperidol, tetrabenazine
Chorea Mnemonic—CHOREA	➢ **C**horea gravidarum ➢ **H**untington's chorea ➢ **O**ral contraceptive pill and DOPA ➢ **R**heumatic chorea ➢ **E**ndocrine disorders (thyrotoxicosis) ➢ **A**rteriosclerotic or senile chorea	Described later
Myoclonus	➢ Encephalitis ➢ Myoclonic epilepsy ➢ Drug overdose, hiccup ➢ Creutzfeldt–Jakob disease ➢ SSPE (subacute sclerosing panencephalitis) ➢ Anoxic encephalopathy (Lance–Adams syndrome)	Correction of underlying disease, sodium valproate (300–12,900 mg/day), clonazepam (0.5–10 mg/day)
Tremors	Described later	
Hemiballismus	Stroke affecting subthalamic nucleus (on contralateral side)	Haloperidol 0.5–2.5 mg TID, tetrabenazine 25–50 mg TID
Dystonia	➢ Kernicterus ➢ Previous brain injury ➢ Familial ➢ Degenerative disorders	Tetrabenazine (dopamine-depleting drug), high-dose anticholinergics, sodium valproate

Q. Write a short note on hemiballismus.

Hemiballismus: Violent flinging movements of the limbs. It is usually unilateral, and hence called hemiballismus. Causes of some important movement disorders are listed in **Table 16.63**.

Parkinson's Disease

Q. Describe the etiology, clinical features/manifestations, diagnosis, and management of Parkinson's disease.

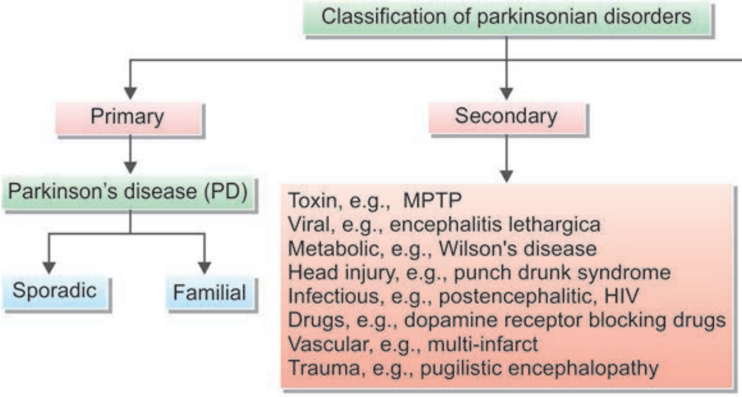
Q. What is parkinsonism? How would you classify parkinsonism?

Q. Discuss the management of idiopathic parkinsonism.

Parkinsonism is a syndrome consisting of a variable combination of **tremor, rigidity, bradykinesia,** and a characteristic **disturbance of gait and posture.**

Classification of parkinsonian disorders (Flowchart 16.9): There are many causes for Parkinsonism but the most common cause is Parkinson's disease (PD).

FLOWCHART 16.9: Classification of parkinsonian disorders.



Classification of parkinsonian disorders
Primary
Secondary
Parkinsonism plus syndrome
Parkinson's disease (PD)
Sporadic
Familial
Toxin, e.g., MPTP
Viral, e.g., encephalitis lethargica
Metabolic, e.g., Wilson's disease
Head injury, e.g., punch drunk syndrome
Infectious, e.g., postencephalitic, HIV
Drugs, e.g., dopamine receptor blocking drugs
Vascular, e.g., multi-infarct
Trauma, e.g., pugilistic encephalopathy

(MPTP: 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine)

Idiopathic Parkinson's Disease (Paralysis Agitans)

- It is a chronic, **progressive disorder** in which **idiopathic parkinsonism** occurs without evidence of more widespread neurologic involvement.
- Parkinson's disease (PD) is distinct from other parkinsonian syndromes both clinically and pathologically.
- **Age and gender:** Its incidence increases sharply with age. PD generally commences in middle or late life and average age of onset is about 60 years. Prevalence is higher in men than women (M:F = 1.5:1). It leads to progressive disability with time.

Etiology

Cause of idiopathic Parkinson's disease is not known. Probably multiple interacting environmental risk factors and genetic susceptibility plays a role.

- **Environmental factors:**
    - Small increased risk with rural living and drinking well water.
    - Pesticide exposure.
    - *Oxidative stress:* Chemical compound 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) is a potent mitochondrial toxin. It causes severe Parkinsonism in young drug users of MPTP by producing oxidative stress leading to death of neuronal cell.
    - Nonsmokers have a higher risk of PD than smokers.
- **Genetic factors:** Genetic factors may play a role and several single genes causing parkinsonism have been identified.
    - *Sporadic:* Idiopathic PD is not usually familial, but there is a significant genetic component in early onset PD (onset before 40).
    - Mutations in many genes has been found in familial cases. Several genetic loci for Mendelian inherited monogenic forms of PD have been identified, designated as PARK 1–11. They are rare but cause early onset and familial PD.

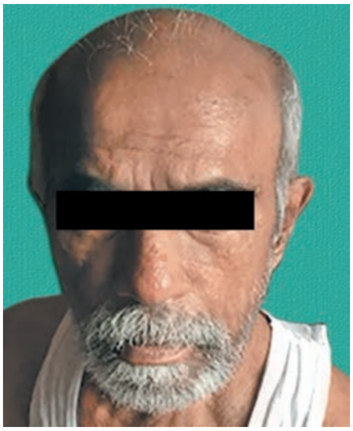
Pathological features

- **Hallmark of PD: Degeneration and depletion of the pigmented dopaminergic neurons** in the substantia nigra pars compacta (SNc), reduced striatal dopamine, and the presence of α-synuclein and intracytoplasmic proteinaceous eosinophilic inclusions in nigral cells known as Lewy bodies.
- Probably environmental or genetic factors alter the α-synuclein protein, rendering it toxic. This leads to formation of Lewy body within the nigral cells. Lewy bodies are also seen in the basal ganglia, brainstem and cortex. Lewy bodies contain tangles of α-synuclein and ubiquitin. They become gradually more widespread and increase as the disease progresses.
- The loss of dopaminergic neurotransmission in the nerve cells (>80%) in the substantia nigra and other nuclei in the midbrain responsible for the symptoms of Parkinson's disease.

Clinical manifestations

A. **Motor symptoms:** Always asymmetrical in onset and become bilateral within a year.

- **Tremor** is an early and presenting symptom in 70% of patients.
    - Frequency is 4–6 Hz tremor and is typically **most prominent at rest** and **worsens with emotional stress**.
    - Typically tremor starts with the fingers and hands at rest.
    - Often described as pill rolling of finger and wrist, because the patient appears to be rolling something between thumb and forefinger. It often begins with rhythmic flexion-extension of the fingers, hand, or foot, or with rhythmic pronation-supination of the forearm. Initially, it may be confined to one limb or to the two limbs on one side before becoming more generalized. It also affects jaw and chin, but not the head.
    - Disappear on voluntary movement and sleep.
- **Rigidity**
    - It is a sign rather than a symptom. Increased **resistance to passive movement** is characteristic clinical feature that accounts for the flexed posture of many patients. Rigidity causes stiffness and a flexed posture.
    - Stiffness on passive limb movement is described as **"lead pipe"** rigidity because the increase in muscle tone is present throughout the range of movement. Unlike spasticity, it is not dependent on speed of movement.
    - When tremor is superimposed on the rigidity, a ratchet like jerkiness is felt, described as **"cogwheel" rigidity**.
- **Akinesia or bradykinesia**
    - Poverty/slowing of movement are the hallmark of **PD. Slowness**/difficulty of initiating **voluntary movement** and an associated **reduction in automatic movements**, such as swinging of the arms when walking.
    - There is **fixity of facial expression** (facial immobility—**mask-like face**) **(Fig. 16.38)**, with widened palpebral fissures and infrequent blinking.
    - Repetitive tapping (at about 2 Hz) over the glabella (Glabellar tap) produces a sustained blink response **(Myerson's sign)**, in contrast to the response of normal subject. Frequency of spontaneous blinking decreases producing a serpentine stare.
    - The **combination of tremor, rigidity, and bradykinesia** results in small, tremulous, and often **illegible/difficult handwriting (micrographia)**. It results in difficulty in activities such as tying shoelaces or buttoning, and difficulty rolling over in bed.
- **Postural changes:** A stooped posture is characteristic feature.
- **Gait changes:** Slow shuffling, freezing and reduced arm swing, small stride length, slow turns, festinating gait (tendency to advance rapid short steps) and catching center of gravity. Feet may be glued to floor. Postural instability and freezing may result in fall forward. Reduced eye blink.
- **Speech and swallowing:** Speech becomes softer (soft voice—hypophonia), quiet, indistinct, flat/monotonous and stuttering. Increased salivation/drooling, and dysphagia (swallowing difficulty is a late feature) which may lead to aspiration pneumonia as a terminal event.
- **Cognitive and psychiatric changes:** Cognitive impairment/dementia, depression, sleep disturbances may be present.

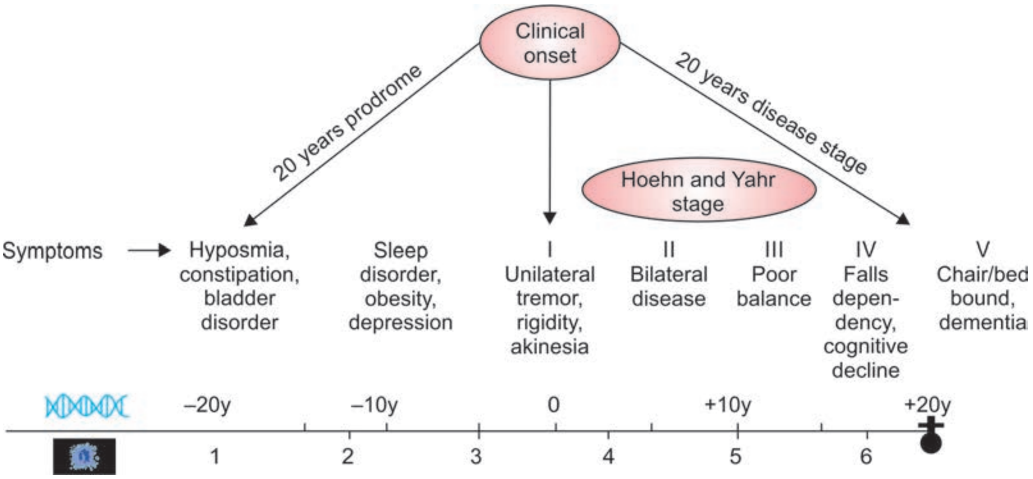


[redacted]

FIG. 16.38: Mask-like facies in Parkinson's disease.

Parkinson's disease timeline has been shown in **Figure 16.39**.

B. **Nonmotor features (Box 16.53):** Some nonmotor symptoms (NMSs) may precede the onset of more typical motor symptoms.



Clinical onset
20 years prodrome
20 years disease stage
Hoehn and Yahr stage
Symptoms
Hyposmia, constipation, bladder disorder
Sleep disorder, obesity, depression
I Unilateral tremor, rigidity, akinesia
II Bilateral disease
III Poor balance
IV Falls dependency, cognitive decline
V Chair/bed bound, dementia

FIG. 16.39: Parkinson's disease timeline.

Box 16.53: Nonmotor symptoms of Parkinsons's disease.

Autonomic dysfunction
- Orthostatic hypotension
- Urinary incontinence
- Constipation
- Sexual problems

Sleep disorders
- Restless legs
- Insomnia
- Daytime somnolence

Neuropsychiatric
- Anxiety
- Depression
- Apathy
- Psychosis
- Dementia

Rheumatological
- Frozen shoulder
- Periarthritis
- Swan neck deformity

Sensory problems
- Reduces sense of smell (hyposmia)
- Pain

Other
- Seborrhea

Investigation/Diagnosis

- Diagnosis is made on **clinical grounds**.
- **Structural imaging** (CT or MRI) is **usually normal**.
- **Functional dopaminergic imaging:** By single-photon emission computed tomography (SPECT) or positron emission tomography (PET) is **abnormal** and shows reduced uptake of striatal dopaminergic markers, particularly in the posterior putamen. However, it is not specific for PD.
- **Dopamine transporter (DaT) imaging:** It is performed by the use of a radiolabeled ligand binding to dopaminergic terminals to know the extent of nigrostriatal cell loss. It may be rarely required to distinguish PD from other causes of tremor, or drug-induced parkinsonism **(Fig. 16.40)**.

Stages of Parkinson's disease **(Table 16.64)**.

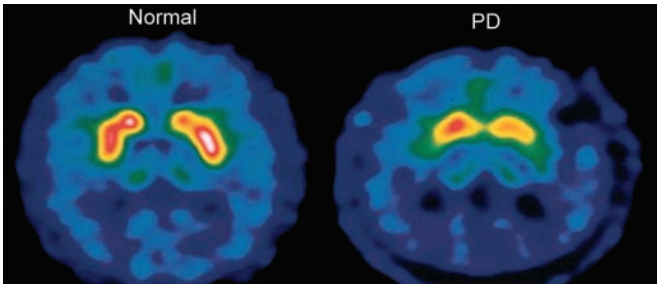

FIG. 16.40: Dopamine transporter (DaT) imaging.

TABLE 16.64: Hoehn and Yahr stage of Parkinson's disease.

Stage	*Disease state*
I	Unilateral involvement only, minimal or no functional impairment
II	Bilateral or midline involvement, without impairment of balance
III	First sign of impaired righting reflex, mild to moderate disability
IV	Fully developed, severely disabling disease; patient still able to walk and stand unassisted
V	Confinement to bed or wheelchair unless aided

Q. Discuss the staging of Parkinson's disease.

Differential diagnosis

Secondary parkinsonism **(Box 16.54)**.

Box 16.54: Causes of secondary parkinsonism.

Toxin: Manganese, 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP), carbon monoxide, mercury, carbon disulfide, cyanide, methanol
Viral: Encephalitis lethargica, Creutzfeldt–Jakob disease
Metabolic: Wilson's disease
Head injury: Punch drunk syndrome
Infectious: Postencephalitic, HIV, SSPE, prion diseases
Drugs: Dopamine receptor blocking drugs, reserpine, tetrabenazine, alpha-methyldopa, lithium, flunarizine, cinnarizine
Vascular: Multi-infarct, Binswanger's disease
Trauma: Pugilistic encephalopathy
Others: Parathyroid abnormalities, hypothyroidism, brain tumors, paraneoplastic, normal pressure hydrocephalus (NPH), psychogenic

TABLE 16.65: Parkinson plus syndromes and its features.

Syndrome	*Features*
Progressive supranuclear palsy (PSP) Steele-Richardson-Olszewski syndrome	Slow ocular saccades, eyelid apraxia, and restricted eye movements with particular impairment of downward gaze and reptilian stare **(Fig. 16.41)**. Frequently experience hyperextension of the neck with early gait disturbance and falls. MRI may reveal a characteristic atrophy of the midbrain with relative preservation of the pons (the "hummingbird sign" on midsagittal images)
Multiple system atrophy (MSA) Parkinsonian (MSA-P) or striatonigral degeneration Cerebellar (MSA-C) or olivopontocerebellar atrophy Autonomic (MSA-A) form or Shy–Drager syndrome	Parkinsonism in conjunction with cerebellar signs and/or early and prominent autonomic dysfunction, usually orthostatic hypotension Cerebellar and brainstem atrophy (the pontine "hot cross buns" sign in MSA-C)
Corticobasal ganglionic degeneration (Rebeiz–Kolodny–Richardson syndrome)	Asymmetric dystonic contractions and clumsiness of one hand coupled with cortical sensory disturbances manifest as apraxia, agnosia, focal myoclonus, or alien limb phenomenon
Dementia with Lewy bodies	Early onset dementia, visual hallucinations
Parkinsonism-dementia complex of Guam	Motor neuron disease plus Parkinson's
Guadeloupean parkinsonism	Levodopa-unresponsive parkinsonism, postural instability with early falls, and pseudobulbar palsy

Q. What are the "Parkinson plus" syndromes?

See **Table 16.65.**

Q. IM19.8 Discuss and describe the pharmacology, dose, side effects and interactions used in the drug therapy of Parkinson's syndrome.

Treatment

A. Symptomatic pharmacologic treatment: Drug treatment in PD is symptomatic rather than curative. None of the currently available drugs are neuroprotective.

- **Anticholinergic drugs**
  - Nonselective muscarinic antagonists are helpful, especially in **relieving tremor.** For example, **trihexyphenidyl, benztropine, and orphenadrine.**
  - Treatment is started with small dose (2 mg), which is gradually built up until benefit occurs or side effects limit further increments.
  - **Adverse effects:** Urinary retention, dry mouth, blurred vision, worsening of glaucoma, constipation, confusion and hallucinosis in elderly. Hence, rarely used as first-line drugs unless patient has severe tremors. They should be avoided in patient above 65 years of age.

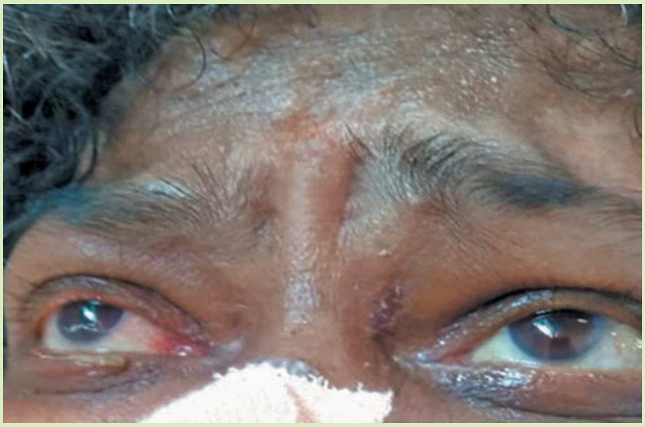

FIG. 16.41: Reptilian stare in progressive supranuclear palsy (PSP).

- **Levodopa**
  - Levodopa, the metabolic precursor of dopamine. It is the single **most effective drug** available for the treatment. It **provides symptomatic benefit** in most patients with parkinsonism and is often particularly helpful in **relieving bradykinesia.** Resolve hypokinesia and rigidity first and tremor later. Levodopa is metabolized by MAO (monoamine oxidase) and COMT (catechol-O-methyl-transferase). Its plasma half-life is around 2 hours. Early use lowers mortality rate. Combined with a dopa decarboxylase inhibitor—benserazide (co-beneldopa) or carbidopa (co-careldopa) to reduce the adverse effects (e.g., nausea and hypotension).

  - **Adverse drug reactions:**
    - Postural hypotension, fluctuations in response.
    - Mydriasis, brownish discoloration of the urine, abnormal smell, transient elevations of transaminases and BUN.
    - GIT effects: Nausea and vomiting.
    - Cardiovascular: Tachycardia, ventricular extrasystoles, atrial fibrillation.
    - Dyskinesias, behavioral disturbances.
  - **"On-off" effect:** Important late complications of levodopa therapy. It is like a light switch; without warning, all of a sudden, person goes from full control to complete reversion back to bradykinesia, tremor, etc. It lasts from 30 minutes to several hours and then get control again. The on-off phenomenon can be controlled in part by reducing dosing, intervals, administering levodopa 1 hour before meals and restricting dietary protein intake or treatment with dopamine agonists.
- **MAO-B Inhibitors**
  - Monoamine oxidase type B **facilitates breakdown of excess dopamine** in the synapse. They produce **asymptomatic motor benefit** when used as a monotherapy and **enhance the efficacy of carbidopa levodopa formulations** when used as adjuncts voided, e.g., selegiline, rasagiline.
  - The addition of selegiline, a monoamine oxidase B inhibitor, reduces the metabolic breakdown of dopamine and may slow down the degeneration in the substantia nigra.
- **Dopamine receptor agonists**
  - Dopamine receptor agonists are classified as ergot derived **(bromocriptine, pergolide and cabergoline)** or nonergot-derived **(pramipexole, ropinirole, rotigotine and apomorphine).**
  - **Side effects:** Produce impulse control disorders (e.g., pathological gambling, binge eating and hypersexuality) and daytime somnolence. Dopamine agonists are contraindicated in patients with psychotic disorders and are best avoided in those with recent myocardial infarction, severe peripheral vascular disease, or active peptic ulceration.
  - Ergot-derived agonists are no longer recommended because of rare but serious fibrotic side effects including cardiac valvular fibrosis.
  - Nonergot dopamine agonists are preferable to ergot-derived dopamine agonists. They are used as an alternative or an addition to levodopa therapy.

Q. Write a short note on COMT (catechol-O-methyltransferase) inhibitors.

- **COMT inhibitors**
  - Catechol-O-methyl-transferase produces peripheral breakdown of levodopa (e.g., **entacapone and tolcapone).** Entacapone prolongs the duration of levodopa by decreasing its peripheral metabolism. The more potent tolcapone is less preferred because of rare but serious hepatotoxicity.
- **Dopamine facilitator**
  - **Amantadine:** It is an antiviral agent that potentiates dopaminergic function by influencing the synthesis, release, reuptake of dopamine. It has a mild antiparkinsonian effect and short-lived effect on bradykinesia. Hence, it is rarely used and are reserved for patients who are unable to tolerate other drugs. Amantadine-either alone or combined with an anticholinergic agent, helpful for mild parkinsonism. It acts by potentiating the release of endogenous dopamine.
  - **Adverse effects:** Livedo reticularis, peripheral edema, confusion and other anticholinergic effects.
- **Peripheral dopamine decarboxylase inhibitors (PDI)**
  - It does not penetrate the BBB; reduce the peripheral metabolism of levodopa. Increase plasma levels of levodopa, prolongs the plasma half-life of levodopa, increase available amounts of dopa for entry into the brain and reduce the daily requirement of levodopa by 75%. For example, **carbidopa, benserazide.**
- **Newer modalities**
  - **Transdermal delivery of rotigotine** improves motor functions.
  - **Subcutaneous apomorphine infusion**
  - **L-dopa infusion into the duodenum**
- Neuroprotective agents that alter pathogenesis
  - MAO inhibitors: Selegiline and rasagiline
  - Antiexcitotoxicity drugs: Riluzole
  - Bioenergetic antioxidant agent, coenzyme Q10
  - Antiapoptotic kinase inhibitors (e.g., CEP-1347)
  - Adenosine A2A receptor antagonists (e.g., **istradefylline**).

B. Surgical treatment

- Indications: Most common indications for surgery in PD are intractable tremor and drug-induced motor fluctuations or dyskinesias.

- Different surgeries are:
  - **Stereotactic surgery** (ventrolateral thalamotomy) tried in unilateral cases.
  - **Pallidotomy** improves tremor and dyskinesia
  - **Deep brain stimulation (DBS):** Stereotactic insertion of electrodes into the brain is most often performed bilaterally and simultaneously. **Best site is subthalamic nucleus.** DBS in these areas alleviates Parkinsonian motor signs particularly during the off periods and reduces troublesome dyskinesias, dystonia and motor fluctuations that result from drug administration. DBS is usually reserved for patients with medically refractory tremor or motor fluctuations.

Newer therapies for PD

Focused ultrasound: Unilateral focused ultrasound lesioning of the STN or thalamus (in tremor-dominant forms of PD) has been found to be beneficial in some patients, particularly if the symptoms are markedly asymmetric.

Cell replacement therapies: Fetal tissue-derived cell transplants—generation dopaminergic neurons from somatic human cells and improvement in the efficacy of differentiation protocols have led to a resurgence of cell transplantation.

Surgical delivery of gene therapy: MRI-guided delivery of adeno-associated viral vector serotype-2 encoding the complementary DNA for the enzyme, aromatic L-amino acid decarboxylase (VY-AADC01) into the putamen.

TABLE 16.66: Characteristic features of extrapyramidal lesion.

Sign	*Site of lesion*
Resting tremor	Substantia nigra, red nucleus
Muscular rigidity	Substantia nigra, putamen
Hypokinesia	Substantia nigra, globus pallidum
Chorea	Caudate nucleus
Hemiballismus	Subthalamic nucleus
Dystonia, athetosis	Putamen

Characteristic Features of Extrapyramidal Lesion

See **Table 16.66.**

Chorea

Q. Write a short note on chorea and mention the disease which causes chorea.

General Features

- Irregular, semipurposeful, abrupt, rapid, brief, jerky, unsustained movements that flow randomly from one part of the body to another. These movements disappear during sleep.
- When choreic movements are more severe, assuming a flinging, sometimes violent, character, they are called ballism.

Causes of Chorea

See **Box 16.55**.

Box 16.55: Causes of chorea.

Rheumatic (Sydenham's chorea)
Huntington's chorea
Encephalitis, e.g., Japanese encephalitis, measles, mumps
Vascular, e.g., HIV-related (toxoplasmosis, progressive multifocal leukoencephalopathy, HIV encephalitis)
Immunologic, e.g., systemic lupus erythematosus, antiphospholipid antibody syndrome, paraneoplastic syndromes, acute disseminated encephalomyelopathy, celiac disease
Drugs, e.g., L-dopa, oral contraceptive, phenytoin
Degenerative disorders of the brain
Benign hereditary
Pregnancy (Chorea gravidarum)
Endocrine-metabolic dysfunction, e.g., adrenal insufficiency, hyper/hypocalcemia, hyper/hypoglycemia, hypernatremia, liver failure
Miscellaneous, e.g., anoxic encephalopathy, cerebral palsy, kernicterus, multiple sclerosis, post-traumatic

Signs in Chorea

- Involuntary protrusion and retraction of the tongue **(jack in the box)**.
- Inability to hold the hands above head with palms facing each other as it results in pronation of arms so that palms face outward **(pronator sign)**.
- Milking action of patient's fingers if asked to grasp the physician's fingers **(milkmaid sign)**.

Sydenham's Chorea (Saint Vitus Dance)

- **Most common cause of chorea in children.**
- It is self-limiting condition, nonsuppurative **complication of group A β-hemolytic streptococcal pharyngitis. It follows acute rheumatic fever** by 4–6 months. Severity varies and disorder may continue for a few months.
- It is due to molecular mimicry between streptococcal and CNS antigens. Infection by group **A β-hemolytic streptococci** in genetically predisposed individual leads to formation of cross-reactive antibodies. These antibodies disrupt the basal ganglia function. Inflammation is seen in caudate nucleus.

- **Clinical features:** It is a **neuropsychiatric disorder**. Clinical features include both **neurological abnormalities** (chorea, weakness and hypotonia) and **psychiatric disorders** (such as emotional liability, hyperactivity, distractibility, obsessions and compulsions). These abnormalities lead to inability to perform normal activities of daily living (ADL) including eating, talking, dressing, writing, walking, learning and socializing, and thus impact negatively on the child's quality of life.
- **Common sign is motor impersistence**. It can be demonstrated by an inability to sustain eye closure or tongue protrusion.
- Evaluation for valvular heart disease is a must. Antistreptolysin-O (ASLO) titers and ESR are often normal.

Treatment

Symptomatic

- Sodium valproate 200–600 mg TID is the first-line drug.
- If valproate is not effective, risperidone, a potent dopamine D2 receptor blocker, may be given to control chorea. The dose is 1–2 mg BID.
- Haloperidol 0.5–1.5 mg BD or TID is used occasionally.
- Other drugs include pimozide, carbamazepine, clonidine, and phenobarbital, levetiracetam.
- Penicillin prophylaxis is necessary to reduce risk of cardiac involvement due to future streptococcal infections.

Huntington's Disease/Chorea

Q. Write a short essay on the transmission and clinical features of Huntington's disease (HD).

Huntington's disease is a progressive, fatal, highly penetrant autosomal dominant disorder characterized by motor, behavioral, and cognitive dysfunction. Onset is typically between the ages of 25 and 45 years.

Etiology

- Huntington's disease is caused by an **increase in the number of polyglutamine (CAG) repeats** (>40) in the coding sequence of the huntingtin gene located on the short arm of chromosome 4.
- The disease manifests earlier if the number of repeats is larger.
- The gene encodes the highly conserved cytoplasmic protein huntingtin, which is widely distributed in neurons throughout the CNS, but its function is not known.

Manifestations

- **Early stages:** Chorea tends to be focal or segmental, but progresses over time to involve multiple body regions. Dysarthria, gait disturbance, and oculomotor abnormalities are common features.
- **Advancing disease:** There may be a reduction in chorea and emergence of dystonia, rigidity, bradykinesia, myoclonus, and spasticity.
- HD patients eventually develop behavioral and cognitive disturbances, and the majority progress to dementia. Depression with suicidal tendencies, aggressive behavior, and psychosis can be prominent features.

Treatment

Multidisciplinary approach, with medical, neuropsychiatric, social, and genetic counseling for patients and their families.

Medical:

- HD chorea is self-limited and is usually not disabling.
- Psychosis can be treated with atypical neuroleptics. Depression and anxiety are treated with appropriate antidepressant and antianxiety drugs.
- No adequate treatment for the cognitive or motor decline.
- Promitochondrial agents such as ubiquinone and creatine are being tested as possible disease-modifying therapies.

Tremor

Q. Write a short note on definition of tremor and mention its types with examples.

Tremor is an unintentional, **rhythmic** muscle movement involving **to-and-fro** movements (oscillations) of one or more parts of the body produced by alternating or synchronous contractions of antagonist muscles. It is the most common of all involuntary movements and can affect the hands, arms, head, face, voice, trunk, and legs.

Causes of Tremor (Box 16.56)

- **Types/Nature of Tremor**
- **Resting tremor** occurs when the muscle is relaxed. For example, tremor occurring when the hands are lying on the lap or hanging next to the trunk while standing or walking. It may be shaking of the limb, even when the individual is at rest. It is usually observed only in the hand or fingers and is seen in Parkinson's disease.

Box 16.56: Causes of tremor.

Physiological: Anxiety
Drugs: Beta-agonists, alcohol
Intention tremor: Cerebellar lesion
Thyrotoxicosis
Drug induced: Amphetamine, steroids
Alcohol withdrawal, liver failure
Mercury poisoning
Wilson's disease (wing-beating tremor)

- **Action tremor** is detected during any type of movement of an affected body part. There are several subtypes of action tremor.
- **Postural tremor** occurs when an individual maintains a position against gravity. For example, holding the arms outstretched.
- **Kinetic tremor** occurs during movement of a part of the body. For example, moving the wrists up and down.
- **Intention tremor** is present during a purposeful movement toward a target. For example, touching a finger to one's nose during a medical examination.
- **Task-specific tremor** occurs when performing highly skilled, goal-oriented tasks. For example, as handwriting or speaking.
- **Isometric tremor** occurs during a voluntary muscle contraction that is not accompanied by any movement.

Classification

Tremor is most commonly classified by its appearance and cause or origin.

- **Essential tremor (benign essential tremor):** It is the most common of the forms of abnormal tremor.
  - It may be mild and nonprogressive or slowly progressive. **Most commonly observed in the hands** but may involve the head, voice, tongue, legs, and trunk. Tremor of the hands is typically present as an action tremor.
  - *Triggers:* Heightened emotion, stress, fever, physical exhaustion, or low blood sugar may trigger tremors and/or increase their severity. It decreases on alcohol consumption.
- **Parkinsonian tremor** is characteristically as a resting tremor.
- **Dystonic tremor** occurs in individuals affected by dystonia. It may affect any muscle. Dystonic tremors occur irregularly and often relieved by complete rest.
- **Cerebellar tremor** is a slow tremor of the extremities that occurs at the end of a purposeful movement (intention tremor). For example, trying to press a button or touching a finger to the tip of one's nose.
  Caused by lesions in or damage to the cerebellum, e.g., stroke, tumor, or MS. Cerebellar damage can also result in a "wing-beating" type of tremor which is a combination of rest, action, and postural tremors. Cerebellar tremor may be associated with dysarthria (speech problems), nystagmus (rapid involuntary movements of the eyes), gait problems, and postural tremor of the trunk and neck.
- **Psychogenic tremor** (functional tremor) can appear as any form of tremor movement. The characteristics may vary but generally include sudden onset and remission, increased incidence with stress. Many individuals have a conversion disorder or psychiatric disease.
- **Orthostatic tremor** detected as rhythmic muscle contractions in the legs and trunk immediately after standing.
- **Physiologic tremor** occurs in every normal individual. It may be exaggerated by strong emotion (such as anxiety or fear), physical exhaustion, etc. It is generally not caused by a neurological disease.
- Rubral tremor/Holmes tremor—seen in midbrain lesions.

Q. IM19.9 **Enumerate the indications for use of surgery and botulinum toxin in the treatment of movement disorders.**

- **Parkinson's disease:** Deep brain stimulation—stimulation of the subthalamic nucleus (STN), improvs almost all parkinsonian symptoms allowing substantial reduction of dopaminergic medication.
- **Essential tremor:** Bilateral thalamic stimulation.
- **Multiple sclerosis tremor:** Stimulation of thalamus [ventralis oralis posterior (Vop)] and the zona incerta.
- **Dystonia:** Thalamotomy, bilateral pallidal deep brain stimulation (DBS).

Botulinum Toxin (BoNT) in Movement Disorders (Fig. 16.42)

- BoNT has been reported to be effective for the treatment of dystonia, bruxism, tremors, tics,

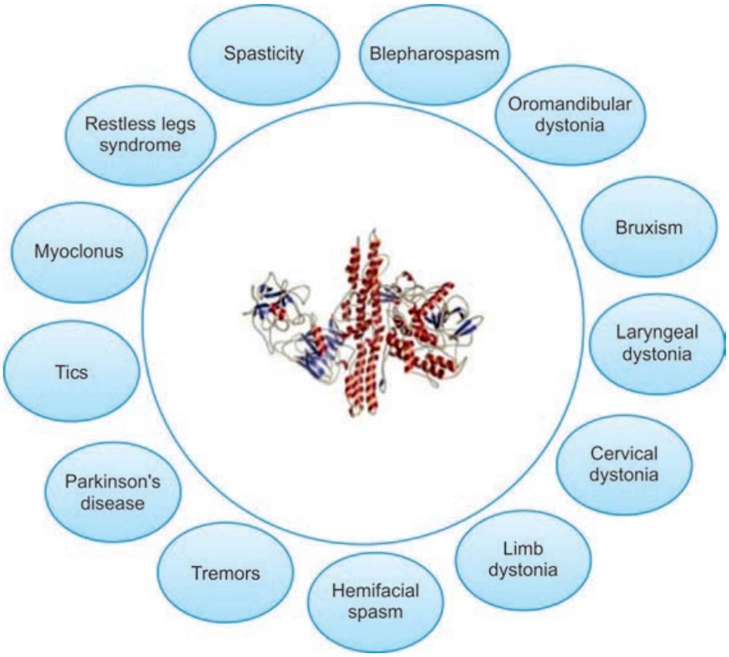

FIG. 16.42: Botulinum toxin in movement disorders.

myoclonus, restless legs syndrome, tardive dyskinesia, and a variety of symptoms associated with Parkinson's disease such as dystonias, lid apraxias, bruxism and flexion of the trunk (camptocormia)

- There are currently four FDA approved BoNT formulations: the three types of botulinum toxin type A (BoNTA), abobotulinumtoxinA and incobotulinumtoxinA/rimabotulinumtoxinB.

ORGANIC BRAIN SYNDROME

Q. Write a short note on organic brain syndrome (OBS).

It is an abnormal mental state characterized by changes in orientation, memory, judgment and affect. It is due to diffuse impairment of brain tissue.

The two most important types of OBS are delirium (*refer* Chapter 20) and dementia is discussed in Chapter 18.

COMA

Q. How would you investigate and manage a 50-year-old patient presenting with coma?

Definitions

Consciousness

- It means the state of patient's awareness of self and environment and his responsiveness to external stimulation and inner need.
- Consciousness is maintained by two separate anatomical and physiological systems:
  i. Ascending reticular activating system (ARAS) projecting from brainstem to thalamus determines arousal (the level of consciousness).
  ii. Cerebral cortex determines the content of consciousness.

Confusion

- Traditionally referred as **"clouding of sensorium"**.
- It denotes inability to think with customary speed, clarity and coherence, accompanied by some degree of inattentiveness and disorientation.
- Confusion results most often from process that influences the brain globally, such as toxic or metabolic disturbance or a dementia.

Drowsiness

- The inability to sustain a wakeful state without application of stimuli externally is called drowsiness.
- Slow arousal is elicited by speaking to the patient or applying a tactile stimulus.

Stupor

- A state in which the person can be aroused only by repeated vigorous stimuli is called stupor.
- There is either absence or slow and inadequate response to spoken commands.
- It is common to find restless or stereotyped motor activity. In these patients there is a reduction in the natural shifting of positions.
- When left unstimulated, these patients quickly return to a sleep-like state.

Lethargic/Drowsiness

Patient can usually be aroused or awakened and may then appear to be in complete possession of her senses, but promptly falls asleep when left alone. It resembles normal sleepiness.

Example: High brainstem disturbances.

Obtundation

It refers to moderate reduction in the patient's level of awareness such that stimuli of mild to moderate intensity fail to arouse; when arousal does occur, the patient is slow to respond.

Coma

Coma is a condition characterized by a deep sleep like stage from which the patient cannot be aroused even with vigorous, continuous stimulation. The patient does not make any localized responses. However, the patient may grimace or show withdrawal responses to painful stimuli.

Classification of Coma

See **Box 16.57.**

Q. Write a short essay/note on causes of coma.

Box 16.57: Classification of coma.

Coma without focal signs or meningism

- **Exogenous intoxicants:** Alcohol, barbiturate, opiates
- **Endogenous metabolic disturbances:** Anoxia, hypoglycemia, diabetic ketoacidosis (DKA), hyperosmolar nonketotic state (HONK), uremia, hepatic failure, hyponatremia or hypernatremia, Addisonian crisis, carbon monoxide poisoning, myxedema
- **Severe systemic infections:** Septicemia, typhoid fever, cerebral malaria, pneumonia, peritonitis, Waterhouse–Friderichsen syndrome
- **Circulatory collapse** (shock) from any cause
- **Postseizure states**
  - Hypertensive encephalopathy
  - Hyperthermia and hypothermia
  - Concussion
  - Acute hydrocephalus

Coma with meningism

- Subarachnoid hemorrhage
- Acute bacterial meningitis
- Viral meningoencephalitis
- Neoplastic meningitis
- Parasitic meningitis
- Pituitary apoplexy

Coma with focal signs

- Hemispheral hemorrhage or massive cerebral infarction
- Brainstem infarction
- Brain abscess, subdural empyema, herpes encephalitis
- Epidural and subdural hemorrhage, brain contusion
- Brain tumor
- Miscellaneous: Thrombotic thrombocytopenic purpura (TTP), fat embolism, ADEM, cortical vein thrombosis, focal infarction caused by bacterial endocarditis

Approach to a Patient with Coma

Q. How do you proceed to investigate and manage a case of coma?

History

Inquire about history of diabetes, hypertension, head injury, convulsions, alcohol or drug use, circumstances in which patient was found, medications in hospitalized patient like anesthetics, sedatives, antiepileptic, opiates, antidepressants, and antipsychotics.

Onset of Coma

- Sudden onset of coma would suggest a vascular cause possibly SAH or brainstem involvement.
- Rapid progression from hemispheric signs to coma—intracerebral hemorrhage.
- Protracted course—tumor, abscess, chronic SDH.
- Altered sensorium (delirium) preceding coma, with no focal neurological deficits indicates metabolic encephalopathy.

General Examination

- **Signs of trauma:** (a) Raccoon eyes, (b) Battle's sign, and (c) CSF rhinorrhea or logorrhea
- **Blood pressure:**
  - Hypertension suggests—(a) hypertensive encephalopathy and (b) intracerebral hemorrhage
  - Hypotension suggests—(a) myocardial infarction, (b) septicemia, (c) Addison's disease, (d) alcohol or barbiturate intoxication, and (e) internal hemorrhage
- **Pulse:** Bradycardia with periodic breathing and hypertension (Cushing reflex) suggests raised ICP.
- **Temperature:**
  - **Hypothermia** suggests—(a) alcohol or barbiturate intoxication, (b) myxedema, (c) advanced tubercular meningitis, and (d) peripheral circulatory failure
  - **Hyperthermia** suggests—(a) systemic infection, (b) meningoencephalitis, (c) heatstroke, and (d) anticholinergic drugs abuse
- **Signs of meningeal irritation:** (a) Meningitis and (b) SAH
- **Fundus:** Raised ICP (papilledema), subhyaloid hemorrhage (SAH), and hypertensive encephalopathy.
- **Smell of breath:** For ketones, alcohol, and hepatic fetor.
- **Skin inspection:**
  - Rash suggests meningococcemia, staphylococcal endocarditis, typhus, Rocky Mountain spotted fever (RMSF)
  - Excessive sweating suggests hypoglycemia or shock
  - Diffuse petechiae suggest thrombotic thrombocytopenic purpura (TTP), disseminated intravascular coagulopathy (DIC), and fat embolism.

Neurological Assessment

- Neurological assessment is done to determine the depth of coma [Glasgow coma scale (GCS)], brainstem function, and lateralization of pathology.
- Observation first without examiner intervention.
- Observe the posture of the limb, position of the eyes and head, spontaneous movement, pattern of respiration.
- Yawning and spontaneous shifting of body position indicates minimal degree of unresponsiveness.
- Multifocal myoclonus almost always indicates metabolic disorder.
- Assess responsiveness by noting patient's reaction to calling his name, or to noxious stimuli such as supraorbital or sternal pressure.

Evaluation of Severity of Coma

See **Box 16.58** and **Table 16.67.**

Q. Write a short essay/note on Edinburgh classification of coma.

Q. Write a short essay/note on Glasgow Coma Scale.

Newer Scales for Prognosis of Coma

FOUR (Full Outline of UnResponsiveness) scale: New Coma Scale is devised in 2005, four components (eye, motor, brainstem, and respiration). Each component has maximum of score of four.

AVPU scale: Alertness, response to Verbal stimuli, response to Painful stimuli, or Unresponsive.

ACDU scale: Alertness, Confusion, Drowsiness, and Unresponsiveness.

Grady scale: Scale of I–V along a scale of confusion, stupor, deep stupor, abnormal posturing, and coma.

Box 16.58: Edinburgh classification of coma.

Grade 0: Fully conscious
Grade 1: Drowsy, but responds to verbal command
Grade 2: Unconscious, but responds to minimal pain stimulus
Grade 3: Unconscious, but responsive to strong pain stimulus
Grade 4: Unconscious, with no response to pain

TABLE 16.67: Glasgow Coma Scale (GCS).

Eye opening		*Best verbal response*		*Best motor response*	
				Obeys commands	6
		Oriented and converses	5	Localizes pain	5
Open spontaneously	4	Converses, but disoriented, confused	4	Exhibits flexion withdrawal	4
Open only to verbal stimuli	3	Uses inappropriate words	3	Decorticate rigidity	3
Open only to pain	2	Makes incomprehensible sounds	2	Decerebrate rigidity	2
Never open	1	No verbal response	1	No motor response	1

Maximum score = **15**
Minimum score = **3**
Coma is equal to GCS of <**8 or less**

Stages of Coma

- **Grade I:** Individuals who respond with recognition when their name is called and **do not lapse into sleep** when left undisturbed.
- **Grade II:** The person lapses into sleep when undisturbed and is aroused only when **a pin is tapped gently over the chest wall**.
- **Grade III:** Patient who winces in response to deep pain stimulus. Deep pain stimulus **may result in abnormal postural reflexes either unilateral or bilateral**.
- **Grade IV:** Deep pain stimulus may result in **decorticate or decerebrate** posturing.
- **Grade V:** The patient who maintains a state of **flaccid unresponsiveness in spite of deep pain stimulation**.

Posture in Comatose Patient

- **Decerebrate rigidity:** It consists of opisthotonus, clenching of jaws, stiff extension of limbs with internal rotation of arms and plantar flexion of feet. Extensor posturing arises in variety of settings: Midbrain compression, cerebellar lesions, metabolic, drug intoxication, etc.
- **Decorticate rigidity:** Arms in flexion and adduction and legs extended signify lesion rostral to midbrain.
- Extensor posture of arms with weak flexor responses of legs is seen with lesions at level of vestibular nuclei.

Brainstem Reflexes (Brainstem Function)

See **Box 16.59.**

Q. Write a short note on brainstem reflexes.

As a rule, when these brainstem activities are preserved, particularly the pupil reactions and eye movements, coma must be ascribed to bilateral hemispheral disease. However, a mass in the hemispheres may cause coma and also produce herniation.

Box 16.59: Brainstem reflexes.

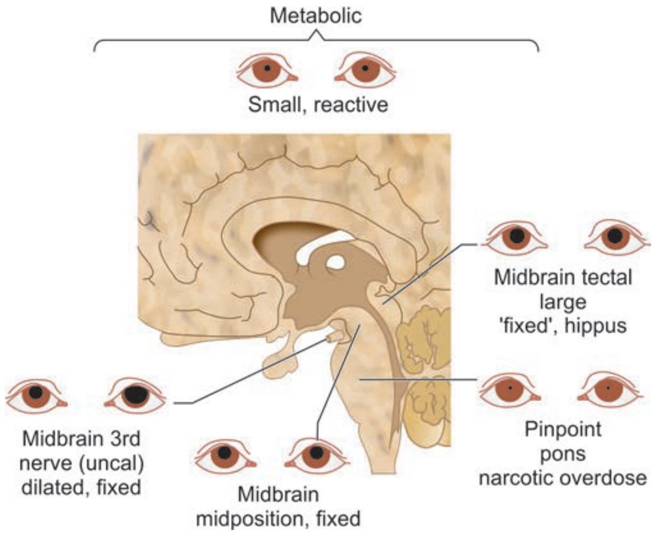
- Pupillary size and reactivity
- Ocular movements
- Corneal responses
- Oculovestibular reflexes
- Pattern of breathing (respiratory pattern)

Pupillary Reactions

See **Table 16.68** and **Figure 16.43.**

TABLE 16.68: Interpretation of pupillary reactions.

Pupillary reactions	*Interpretation*
Symmetrically reactive round pupils	Exclude midbrain damage
Enlarged and unreactive pupil (>5 mm)	Intrinsic midbrain lesion (ipsilateral) or by ipsilateral mass
Oval and slightly eccentric pupils	Early midbrain or IIIrd nerve compression
Bilateral dilated and unreactive pupils	Severe midbrain damage by transtentorial herniation or anticholinergic drugs toxicity (atropine, TCA)
Dilatation of one pupil that then becomes fixed to light	Compression of the IIIrd cranial nerve and is a neurosurgical emergency
Reactive bilaterally small but not pinpoint (1–2.5 mm)	Metabolic encephalopathy or thalamic hemorrhages
Bilateral pinpoint (very small <1 mm) but reactive pupil	Opioid or barbiturate overdose or bilateral pontine hemorrhage
Bilateral midpoint reactive pupils (i.e., normal pupils)	Metabolic comas, coma due to sedative drugs except opiates
Bilateral light fixed, dilated pupils	Cardinal sign of brain death in deep coma of any cause, but particularly in barbiturate intoxication and hypothermia



Metabolic
Small, reactive
Midbrain tectal
large
'fixed', hippus
Midbrain 3rd

FIG. 16.44: Eye movements and position.

Eye Movements and Position (Fig. 16.44)

- In light coma of metabolic origin, eyes wander conjugately from side to side in random fashion. These movements disappear as coma deepens.
- **Adducted eye at rest:** VIth nerve palsy. If it is bilateral, it is due to raised ICT.
- **Abducted eye at rest:** IIIrd nerve palsy.
- **Conjugate deviation of eyes toward hemispheric** lesion and away from unilateral pontine lesion.
- **Downward and inward deviation of eyes:** Lesions of thalamus and upper midbrain.
- **Eyes turn toward convulsing side in focal** seizures.
- **Ocular bobbing:** It is characterized by brisk downward and slow upward movements of the eyes associated with loss of horizontal eye movements. It is diagnostic of lesions in midbrain and pons.
- **Ocular dipping:** It is characterized by slow downward followed by faster upward movement in patients with normal horizontal gaze. It indicates diffuse cortical anoxic damage and drug intoxication.
- **Disconjugate eyes (divergent ocular axes):** Brainstem lesion, e.g., skew deviation (one eye up, one eye down)
- **Oculocephalic reflex:** Also called doll's eye movement.
    - Elicited by briskly turning or tilting the head.
    - In coma of metabolic origin or due to lesions of bihemispheral structures, the response consists of conjugate movements of eyes in the opposite direction.

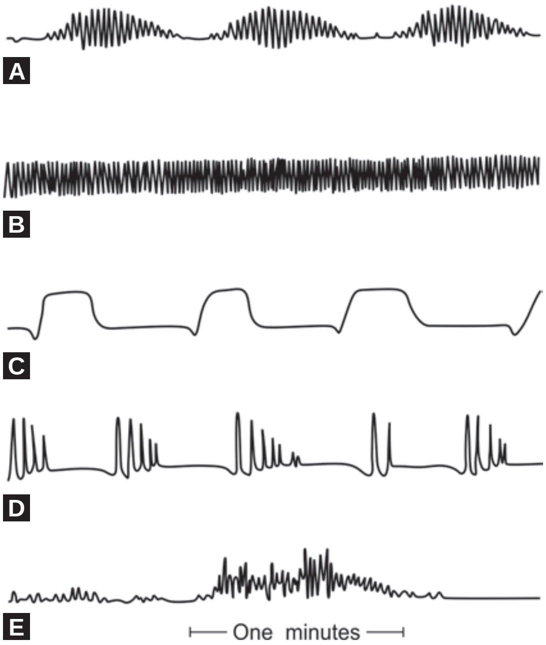
  - Positive response indicates: Intact oculomotor, abducent, midbrain, and pons.
  - Absent reflex indicates: Damage within brainstem. It can be also due to profound overdose of sedatives or anticonvulsants.

Oculovestibular or Caloric Test

- **Method:** Irrigate the external auditory canal with cold water.
- **Normal response:** Causes slow conjugate deviation of eyes toward irrigated ear followed in few seconds by compensatory nystagmus (i.e., fast component away from irrigated ear).
- **Interpretation:**
  - Loss of conjugate ocular movements in brainstem damage.
  - Loss of fast corrective nystagmus in metabolic or bilateral hemispheral damage. The eyes are tonically deflected to side irrigated with cold water and this position may be held for 2–3 minutes.

Respiratory Patterns (Figs. 16.45A to E)

- **Slow, shallow, regular breathing:** Metabolic or drug depression.
- **Cheyne-Stokes respiration** (alternating hyperpnea and periods of apnea): Massive supratentorial lesions, bilateral cerebral lesions and mild metabolic disturbance.
- **Central neurogenic hyperventilation:** Lesions of lower midbrain and upper pons either primary or secondary to transtentorial herniation.
- **Apneustic breathing:** Lower pontine lesions.
- **Biot's or ataxic breathing:** Lesions of dorsomedial part of medulla.
- **Agonal gasps:** Bilateral lower brainstem damage and terminal respiratory pattern.
- **Acidotic (Kussmaul) respiration** (deep, sighing hyperventilation): In diabetic ketoacidosis and uremia.



FIGS. 16.45A TO E: Respiratory patterns: (A) Cheyne-Stokes respiration; (B) Central neurogenic hyperventilation; (C) Apneustic breathing; (D) Cluster breathing; (E) Ataxic/Biot's breathing.

Laboratory Studies and Imaging

- Complete blood count
- Random blood sugar
- Renal function tests and liver function tests
- Serum electrolytes
- Urine examination for specific gravity, glucose, acetone, and protein content
- Arterial blood gases analysis: For acidosis or high CO levels
- Chest X-ray
- ECG
- CT or MRI scan: Quick and effective in demonstrating all types of brain hemorrhage and mass lesions.
- Lumbar puncture: It should be performed in coma only after careful risk assessment. It should not be performed when there is a suspicion of an intracranial mass lesion. CSF examination may help in the diagnosis of meningoencephalitis or other infection, or in subarachnoid hemorrhage.
- EEG: It may be useful in the diagnosis of metabolic coma, encephalitis, and nonconvulsive status epilepticus.
- **Drugs screen:** Blood alcohol and salicylates, urine toxicology (e.g., screening for benzodiazepines, narcotics, amphetamines, etc.).
- Others, e.g., cerebral malaria and porphyria.

Differential Diagnosis

- **Coma vigil (vegetative state—VS):** Patient is comatose, but the eyelids are open giving the appearance of being awake. Patients can open their eyes or have random limb and head movements but there is complete absence of response to commands or to communicate. It is usually due to extensive cortical damage. Brainstem function is intact. Hence, breathing is normal without the need for mechanical ventilation. Patients may remain in this vegetative state for years. Even after 12 months if there is no recovery, it is called permanent vegetative state (PVS).

- **Minimally conscious state (MCS):** A condition in which patient has some limited/inconsistent (fluctuating) signs of awareness (unlike patients with vegetative state). These include nonreflexive response to sensory stimulation, awareness of the self or the environment, or language comprehension or expression.
- **Akinetic mutism:** It refers to a state in which the patient is partially or fully awake but remains entirely silent and immobile. The patient does nothing voluntarily and has sleep/wake cycles and can maintain vital functions. It may be seen in bilateral frontal lobe lesions, hydrocephalus and a mass in the region of third ventricle.
- **Locked-in-state (locked-in syndrome or pseudocoma):** The patient is fully aware and alert but unable to communicate except through eye movements. There is complete paralysis except vertical eye movements and intact lid movements (blinking in ventral). This syndrome is due to extensive transverse lesions in the pontine and midbrain (infarction).
- **Conversion reaction:** Patients have normal pupils, corneal reflexes, and plantar reflexes. These patients may keep their eyes firmly closed and resist the opening of the eye by examiners. Their eyes roll up when the lids are raised. It may be due to feigned or hysterical state.
- Psychogenic coma.
- Brainstem death is discussed below.

Treatment

- **General management:** Comatose patients require careful nursing, maintenance of the airway, and breathing frequent monitoring of vital functions.
- **Specific treatment:** Diagnosis of the underlying cause/lesion should be done as early as possible and appropriate specific treatment is to be given. For example:
  - **Diabetic with hypoglycemic coma:** Administer hypertonic glucose without waiting for reports. However, bedside estimation of blood glucose and administer dextrose only if the blood glucose is below 100 mg/dL.
  - **Alcoholic with coma:** Administer glucose and vitamin B_1 100 mg intravenously, without waiting for reports.
- **Long-term management**
  - **Skin care:** Change the posture every 2–3 hours and keep the skin clean and dry to avoid pressure/bed sores and pressure palsies.
  - **Eye care:** To prevent corneal damage (lid taping, irrigation).
  - **Oral hygiene:** Mouthwashes and suction.
  - **Fluids:** Through nasogastric tube or IV. Have a secure IV line.
  - **Feeding:** Nutrients through a fine-bore nasogastric tube.
  - **Sphincters:** Catheterization of urinary bladder and rectal evacuation.
  - **Posture of the patient:** Prevent the aspiration of gastric contents by positioning the patient in prone or lateral position.

Brain Death

Q. Write a short note on brain death.

Brain death occurs from irreversible brain injury which is sufficient to permanently eliminate all cortical and brainstem function (i.e., loss of all functions of the brain, including the brainstem).

- Because the vital centers in the brainstem maintain cardiovascular and respiratory functions, brain death is incompatible with survival despite mechanical ventilation and cardiovascular and nutritional supportive measures.
- It develops when intracranial pressure (ICP) exceeds cerebral perfusion pressure (CPP) and results in cessation of CBF and oxygen delivery.
- **Significance of brain death:**
  - It permits the withdrawal of costly lifesaving equipment and drugs.
  - Family can be offered the opportunity for organ donation.

Diagnosis of Brain Death

Brain death is a **clinical diagnosis.** No other tests are necessary and complete clinical examination including independent brain death determinations by two licensed physicians is conclusive.

Clinical Evaluation (Prerequisites)

- Establish known irreversible cause of coma.
- The first and foremost critical step in establishing the diagnosis of brain death is to **establish an irreversible, untreatable cause of the brain injury** (e.g., global ischemia due to cardiac arrest, intracranial bleed, and severe head injury).

- **Exclude** potentially **reversible conditions** like hypothermia, drug intoxication, poisoning, metabolic disorders (e.g., hypoglycemia, acidosis, and electrolyte imbalance). Hypothermia should also be excluded—rectal temperature must exceed 35°C.
- Achieve body temperature >36°C.
- Achieve normal systolic BP (>100 mm Hg)

Clinical Evaluation (Neuroassessment)

- **Establish coma**
- **Establish absence of brainstem reflexes**
  - Pupillary reflex (absent)
  - Eye movements
    - Oculocephalic: Absent (doll's eye movements)
    - Oculovestibular: Absent (cold caloric test)
  - Facial sensation and motor response: No corneal reflex, no jaw reflex, no grimacing to deep pressure on nail bed, supraorbital ridge or temporomandibular joint
  - Pharyngeal (gag) reflex absent
  - Tracheal (cough) reflex absent.

Establish Apnea by Apnea Test

Prerequisites for apnea test: Body temperature >36°C, systolic blood pressure >100 mm Hg, normal electrolytes profile, and normal $PaCO_2$ (35–45 mm Hg).

Procedure of apnea test:

- Connect a pulse oximeter and disconnect the ventilator.
- Deliver 100% O_2 by catheter through endotracheal tube at 6 L/minute.
- Observe for respiratory movement at least for 8–10 minutes.
- Discontinue testing: If BP drops to <90 mm Hg and PaO_2 decreases to 85% by pulse oximetry for 30 seconds.
- **If respiratory drive/movement** is observed after 8 minutes. Take next blood sample for blood gas studies. This indicates apnea, test result is negative.
- **Absence of respiration drive: If respiratory movements are absent** and arterial $PaCO_2$ is 60 mm Hg or 20 mm Hg increase over a baseline, normal $PaCO_2$ indicates apnea, **test** result is **positive** and **supports the clinical diagnosis of brain death**.

Ancillary Tests/Confirmatory Testing

- **EEG:** Electrocerebral silence absence of electrical activity during at least 30 minutes.
- **Cerebral angiography:** Absence of intracranial blood flow.
- **PET:** Glucose metabolism studies/dynamic nuclear brain scan: "Hollow skull" sign of brain death.

Documentation

Time of death is the time the arterial $PaCO_2$ reached the target value or when ancillary test officially interpreted.

Box 16.60: Common causes of anosmia.

- **Local causes**
  - Acute local inflammation
  - Heavy smoking
  - Atrophy of bulb
  - Chronic kidney diseases
- **Syndromes associated**
  - **Foster Kennedy syndrome** (anosmia, optic atrophy of one eye and contralateral eye papilledema due to tumor in brain)
  - **Pseudo-Foster-Kennedy syndrome** (above features in absence of tumor)
- **Systemic causes**
  - Parkinsonism
  - Meningitis
  - Head trauma
  - Intracranial tumors
  - Endocrine diseases
    - Diabetes mellitus
    - Hypothyroidism
    - Kallmann syndrome
    - Turner syndrome
  - Vitamin B_{12} deficiency

DISEASES OF CRANIAL NERVES

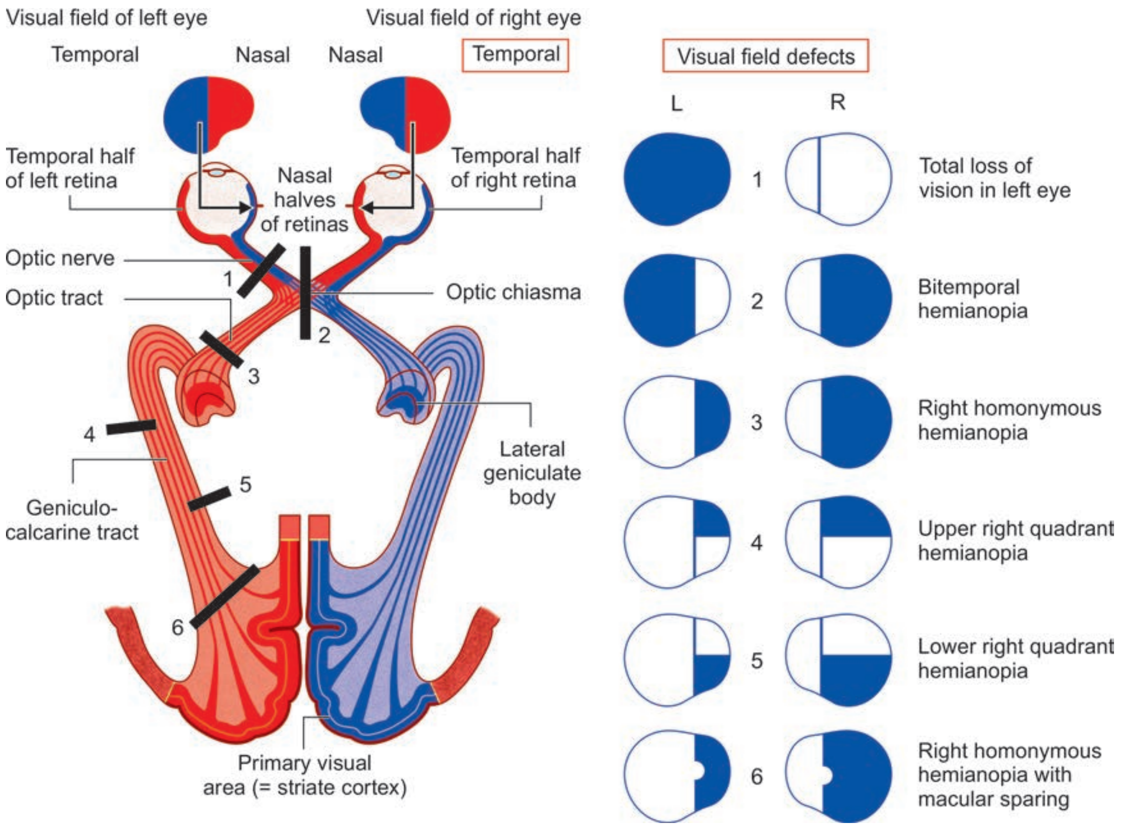
Ist Cranial Nerve: Olfactory Nerve

Common causes of anosmia have been shown in **Box 16.60**.

IInd Cranial Nerve: Optic Nerve

Clinical Examinations

Optic nerve is tested by various modalities of vision: Visual acuity, visual fields, color vision, and fundoscopy.



Visual field of left eye
Visual field of right eye
Temporal
Nasal
Nasal
Temporal

Total loss of vision in left eye
Bitemporal hemianopia
Right homonymous hemianopia
Upper right quadrant hemianopia
Lower right quadrant hemianopia
Right homonymous hemianopia with macular sparing

FIG. 16.46: Various visual field defects depending on the location of lesion.

Visual acuity

- Snellen chart is used to measure visual acuity for distant vision.
- Visual acuity for near vision is tested by Jaeger's chart.

Pathway of optic nerve ***(Fig. 16.46)***

Q. Discuss the field defects produced and localization of lesions at various levels.

Visual fields

- Visual can be impaired by damage to the visual system anywhere from the eyes to the occipital lobes.
- One can localize the site of the lesion with considerable accuracy by mapping the visual field deficit by finger confrontation and then correlating it with the topographic anatomy of the visual pathway.
- At the optic chiasm, fibers from nasal ganglion cells decussate into the contralateral optic tract. Symmetric compression of the optic chiasm by a pituitary adenoma, meningioma, craniopharyngioma, glioma, or aneurysm results in a bitemporal hemianopia.
- A unilateral postchiasmal lesion leaves the visual acuity in each eye unaffected, although the patient may read the letters on only the left or right half of the eye chart.
- Damage to the optic radiations in the temporal lobe (Meyer's loop) produces a superior quadrantic homonymous hemianopia, whereas injury to the optic radiations in the parietal lobe results in an inferior quadrantic homonymous hemianopia.
- Lesions of the primary visual cortex give rise to dense, congruous hemianopic field defects by posterior cerebral artery infarct. They have macular sparing, because collaterals from the middle cerebral artery supply the macular representation at the tip of the occipital lobe.
- Destruction of both occipital lobes produces cortical blindness. This condition can be distinguished from bilateral prechiasmal visual loss by noting that the pupil responses and optic fundi remain normal.

Visual loss: Lesions in any area between the retina and the visual cortex can produce visual loss. Patterns of visual field loss are shown in **Figure 16.46**.

- **Visual symptoms involving one eye:** Due to lesions anterior to the optic chiasm.
- **Transient visual loss:** It is the sudden onset of visual loss lasting <15 minutes. It is usually due to vascular disease and may be difficult to identify whether the visual loss was monocular (carotid circulation) or binocular (vertebrobasilar circulation).

Color vision

- The retina has three classes of cones, with visual pigments of differing peak spectral sensitivity: red (560 nm), green (350 nm), and blue (430 nm).
- The red and green cone pigments are encoded on the X chromosome; the blue cone pigment on chromosome 7.
- Most common anomalies of color vision are the various types of red-green deficiency inherited as sex-linked recessive condition. Only males are affected (X-linked) and present in 8% males.
- Ishihara color plates can be used to detect red-green color blindness.
- Acquired defects of color vision occur in macular and optic nerve diseases, and due to certain drugs (e.g., ethambutol and chloroquine).

Papilledema (Fig. 16.47)

Q. List the causes of papilledema.

Papilledema is the edema (swelling) of the optic disk >3 diopters. This term has been used only for passive swelling of the optic disk secondary to raised ICP.

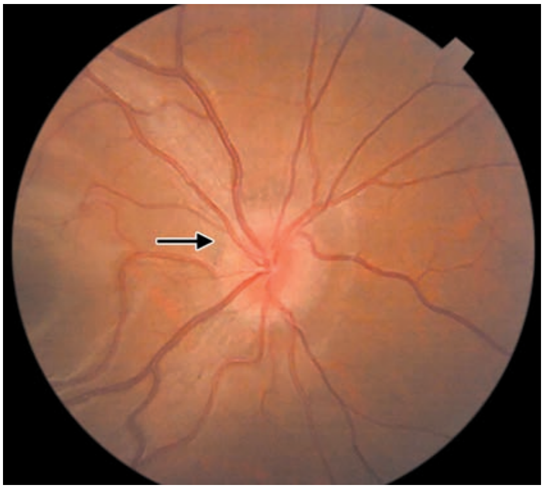

FIG. 16.47: Fundoscopy showing papilledema (arrow).

Box 16.61: Causes of papilledema.

Optic nerve damage

- Demyelination (optic neuritis/papillitis)
- Anterior ischemic optic neuropathy
- Toxins (e.g., methanol)
- Infiltration of optic disk by glioma, lymphoma, and sarcoidosis

Ocular blockage of venous drainage

- Central retinal venous block
- Cavernous sinus thrombosis

Raised intracranial pressure

- Cerebral mass lesion (tumor, abscess granulomas)
- Obstructive hydrocephalus, diffuse brain edema
- Idiopathic intracranial hypertension
- Cerebral venous sinus thrombosis

Systemic disorders affecting retinal vessels

- Hypertension
- Vasculitis: Giant cell arteritis and other autoimmune vasculitides
- Hypercapnia, hypercalcemia
- COPD (hypercapnia)

Causes of papilledema (Box 16.61)

It develops due to obstruction of venous outflow along with stasis of axoplasmic flow within the optic nerve. It also develops due to any cause that produces edema in the head of the optic nerve (e.g., local causes).

Argyll Robertson Pupil

Q. List the causes and eye findings in Argyll Robertson pupil.

It is the pupillary change where accommodation reflex is present but light reflex is impaired.

Findings (Box 16.62) and causes (Box 16.63)

Site of lesion: Tectum of the midbrain or peripherally in the branch of IIIrd cranial nerve.

Box 16.62: Ophthalmological findings in Argyll Robertson pupil.

- Pupils: Small, irregular, and unequal in size
- Iris: Atrophy and depigmentation
- Light reflex: Absent for direct (always) and consensual (usually stimulus)
- Accommodation reflex: Intact
- Ciliospinal reflex: Absent

Box 16.63: Causes of Argyll Robertson pupil.

- Neurosyphilis (tabes dorsalis) generally bilateral
- Diabetes
- Multiple sclerosis
- Sarcoidosis
- Tumors of pineal region

Pinpoint Pupil

Q. List the causes of pinpoint pupil.

Causes of pinpoint pupil

See **Box 16.64**.

Box 16.64: Causes of pinpoint pupil.

- Pontine hemorrhage
- Organophosphorus poisoning
- Opium poisoning
- Pilocarpine instillation
- Thalamic hemorrhage (occasionally)

Adie's Pupil

Q. Write a short note on Adie's pupil.

- Normally, pupil reaction to light is absent or markedly reduced when tested in the routine examination. However, Adie's pupil reacts slowly with prolonged maximal stimulation.
- Once the Adie's pupil reacts to accommodation, the pupil remains tonically constricted and dilates very slowly.
- **Cause:** Destruction of ciliary ganglion.

Blindness

Q. Write a short note on causes of blindness.

Causes of blindness

See **Box 16.65**.

Box 16.65: Causes of blindness.

- Cataract leading cause (47.9%)
- Glaucoma (12.3%)
- Age-related macular degeneration (AMD) (8.7%)
- Corneal opacities
- Diabetic retinopathy
- Childhood blindness
- Trachoma

Horner's Syndrome (Figs. 16.48A and B)

Q. Write a short essay/note on Horner's syndrome.

- Horner's syndrome is a syndrome complex caused by the involvement of the oculosympathetic tract.
- **Sympathetic nervous supply to the eye** consists of three-neuron pathway:
  1. Fibers through the IIIrd nerve innervate levator muscle of eyelid (Muller's muscles).
  2. Fibers through nasociliary nerve supply the blood vessels of eye.
  3. Fibers through long ciliary nerve innervate pupil.
- Damage to any part of the pathway results in Horner's syndrome.

FIGS. 16.48A AND B: Left Horner's syndrome.

Components of Horner's Syndrome

See **Box 16.66**.

Box 16.66: Components of Horner's syndrome.

- Miosis due to reduced pupillodilator activity
- Partial ptosis of eyelid
- Enophthalmos
- Anhidrosis of ipsilateral half of face
- Absence of ciliospinal reflex

Causes of Horner's Syndrome

- **Cerebral and brainstem lesions:** Hemispherectomy, massive cerebral infarction, brainstem demyelination
- **Cervical cord lesions:** Syringomyelia and cord tumors (e.g., ependymoma, glioma)
- **Thoracic root level:** Apical lung tumor (pancoast "tumor") or TB, cervical rib, trauma to brachial plexus
- **Sympathetic chain and carotid artery in neck:** Following thyroid/laryngeal/carotid surgery, carotid artery dissection, neoplastic infiltration, cervical sympathectomy
- **Miscellaneous:** Congenital Horner's syndrome, cluster headache (transient), idiopathic.

IIIrd, IVth, and VIth Cranial Nerves: Oculomotor, Trochlear, and Abducens Nerves

Ptosis (Fig. 16.49)

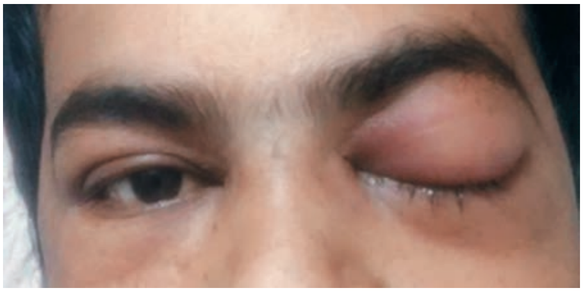

FIG. 16.49: Unilateral ptosis.

- Normal palpebral fissure 9–12 mm.
- The **narrowing of the palpebral fissures due to inability to open an upper eyelid** is called ptosis.
- Ptosis may be congenital or acquired, unilateral or bilateral, partial or complete
  - **Congenital ptosis:** It is due to bilateral congenital hypoplasia of the IIIrd nerve nuclei, and results in bilateral ptosis.
  - **Acquired ptosis:** Acquired ptosis may be unilateral or bilateral.

Causes of ptosis (Tables 16.69 and 16.70)

TABLE 16.69: Causes of ptosis.

1. **Congenital ptosis** 2. **Acquired ptosis**	
Neurogenic	➢ Horner's syndrome ➢ IIIrd nerve palsy
Neuromuscular disorder	➢ Myasthenia gravis (fatigable ptosis) ➢ Poisoning (snakebite/botulism)
Myogenic	➢ Mitochondrial myopathy ➢ Oculopharyngeal muscle dystrophy ➢ Myotonic dystrophy
Mechanical ptosis	Due to eyelid edema or tumors

TABLE 16.70: Causes of unilateral and bilateral ptosis.

Unilateral ptosis	*Bilateral ptosis*
➢ IIIrd cranial nerve lesion ➢ Lesion of cervical sympathetic pathway (Horner's syndrome) ➢ Lesions of the upper eyelid	➢ Myopathies ➢ Myasthenia gravis ➢ Bilateral Horner's syndrome ➢ Snakebite ➢ Botulism

Q. Write a short note on the causes of ptosis.

- **Partial ptosis:** This occurs with lesion of the cervical sympathetic pathway (Horner's syndrome) due to weakness of the tarsal muscles, innervated by cervical sympathetic nerves. The upper eyelids can however be raised voluntarily.
- **Complete ptosis:** This occurs with IIIrd nerve lesions due to paralysis of the levator palpebrae superioris, innervated by the IIIrd nerve. The patient is not able to voluntarily open the affected eye.

Ptosis and Pupillary Size

- Ptosis with a small pupil: Horner's syndrome
- Ptosis with a large pupil: IIIrd nerve palsy (compressive lesions).
- Ptosis with normal papillary size: Infarction of IIIrd nerve, myasthenia gravis, myopathies or GBS.

Ophthalmoplegia

- Ophthalmoplegia is the paralysis or weakness of the eye muscles.
- **Supranuclear ophthalmoplegia**—also called gaze palsies. It is due to involvement of corticonuclear fibers of the IIIrd, IVth, and VIth cranial nerves.
- **Internuclear ophthalmoplegia**—due to involvement of medial longitudinal fasciculus (MLF) and paramedian pontine reticular formation (PPRF) which connect the IIIrd nerve to the contralateral VIth nerve.
- **Nuclear/Infranuclear ophthalmoplegia**—involvement of individual cranial nerves (CN III, IV, and VI).
- **Internal ophthalmoplegia**—paralysis of constrictor pupillae and ciliary muscle.
- **External ophthalmoplegia**—paralysis of extraocular muscles.
- **Total ophthalmoplegia**—combination of external and internal ophthalmoplegia.

Vestibular nucleus (VN)

FIG. 16.50: Lesions of medial longitudinal fasciculus (MLF).

Internuclear Ophthalmoplegia (Fig. 16.50)

Q. **Write a short note on internuclear ophthalmoplegia.**

- It is caused by a lesion of the MLF, which carries signals from the abducens nucleus to the contralateral medial rectus oculomotor subnucleus.
- The abducens nerve and MLF coordinate conjugate horizontal eye movements with co-contraction of ipsilateral lateral rectus and contralateral medial rectus muscles.
- Classic signs of unilateral internuclear ophthalmoplegia include impaired adduction of the ipsilesional eye and abducting nystagmus of the contralateral eye.
- Despite ipsilateral adduction weakness with direct motility testing, adduction is often intact with convergence because convergence signals to the medial rectus nucleus are distinct from the MLF.
- Multiple sclerosis and microvascular brainstem ischemia are the most common causes.

Diplopia

Q. **Write a short note on diplopia.**

Diplopia means double vision. Most common subjective complain elicited by lesions in the oculomotor system. It occurs more frequently with lesions of the extraocular muscles or oculomotor nerves than with supranuclear lesions which result in gaze palsies.

- **Monocular diplopia**
  - The first point to clarify is whether diplopia persists in either eye after covering the fellow eye. If it does, the diagnosis is monocular diplopia.
  - The cause is usually intrinsic to the eye. For example, corneal aberrations, uncorrected refractive error, cataract, or foveal traction may give rise to monocular diplopia.
- **Binocular diplopia**
  - Diplopia alleviated by covering one eye is binocular diplopia and is caused by disruption of ocular alignment, occurs only if both eyes are open.
  - Binocular diplopia occurs from a wide range or processes. For example, infectious, neoplastic, metabolic, degenerative, inflammatory, and vascular.
  - Here two images, one real and one false are formed. The real image is closer to the eye and distinct; the false image is farther away from eye and indistinct.

Nystagmus

Q. List the causes of nystagmus.

Nystagmus is involuntary, conjugate, repetitive and rhythmic movement of eyeballs. It is a sign of disease of the retina, cerebellum and/or vestibular systems, and their connections.

Types of nystagmus (Table 16.71)

TABLE 16.71: Types of nystagmus.

Pendular nystagmus	***Jerk nystagmus***			***Nystagmus of dissociated rhythm***
In this time of amplitude of nystagmus is equal in either directions	In this type of nystagmus, there is slow component followed by fast (jerk) component due to cortical correction.			Usually gaze-evoked nystagmus
	Horizontal	**Vertical**	**Rotatory**	
These are predominantly seen in congenital conditions especially due to visual defects from earlier years	➢ Labyrinthine disorders ➢ Cerebellar disorders ➢ Uppermost cervical lesion	➢ Never labyrinthine ➢ Cerebellar disorders ➢ Brainstem lesions ➢ Drugs like benzodiazepines, barbiturate	➢ Labyrinthine disorders ➢ Brainstem lesions	➢ Medial longitudinal fasciculus (MLF) lesions ➢ Multiple sclerosis

Other common types of nystagmus

	Description	***Condition seen***
See-saw nystagmus	Upward deflection of one eyeball with downward deflection on the contralateral eyeball	Suprasellar region anterior to IIIrd ventricle
Upbeat nystagmus	Fast movement upward	Lesions in the vermis of the cerebellum
Downbeat nystagmus	Fast component is down	Foramen magnum lesions
Optokinetic nystagmus	Railway track nystagmus	Deep parietal lobe lesions
Convergence-retraction nystagmus	Attempted upgaze provokes jerk nystagmus with fast component in inward convergent manner	Lesion at superior colliculus—Parinaud's syndrome

Vth Cranial Nerve: Trigeminal Nerve

Q. Discuss the clinical features and management of trigeminal neuralgia.

Trigeminal Neuralgia (Tic Douloureux)

- Trigeminal neuralgia is also known as **prosopalgia or Fothergill's disease**. Tic Douloureux means painful jerking.
- It is a neuropathic disorder. It is defined as sudden, episodes of usually unilateral, severe, brief, stabbing, intense, lancinating, recurring pain in the distribution of one or more branches of the Vth cranial nerve (trigeminal nerve).
- Middle age and later. Usually, it starts in the 6th and 7th decades and major risk factor is hypertension.

Etiology

Usually produced due to compression of the trigeminal nerve at or near the pons by an ecstatic vascular loop. Pain like trigeminal neuralgia can be seen in other conditions **(Box 16.67)**.

Clinical features

Pain

- **Characteristics of pain:** Sudden, unilateral, intermittent (paroxysmal), sharp, shooting/knife-like/lancinating/electric shock-like. Pain rarely crosses the midline. In extreme cases, the patient will have a motionless face known as the "frozen or mask-like face". In 10–12% of cases it is bilateral and usually due to intrinsic brainstem pathology (e.g., MS) or expanding cranial tumor (acoustic schwannomas, meningiomas, epidermoids).
- **Duration of pain:** Pain is of short duration (lasting seconds), but may recur with variable frequency (may be many times a day). Attacks do not occur during sleep.
- Pain occurs along the cutaneous distribution of the Vth nerve (full or branches). Pain usually commences in the mandibular division but may spread to involve the maxillary and occasionally the ophthalmic divisions.

Box 16.67: Causes of trigeminal neuralgia.

- Usually idiopathic
- Demyelination
- Multiple sclerosis
- Petrous ridge compression
- Post-traumatic neuralgia
- Intracranial tumors
- Intracranial vascular abnormalities
- Viral etiology

- Pain is precipitated by minor trauma to the trigger zones (e.g., slight touch, chewing, shaving, rinsing mouth, exposure to cold wind). Common trigger zones can be external/cutaneous (around the ala of nose, corners of lips and check) or internal/intraoral (teeth, gingivae, tongue). Trigger area on the face are so sensitive that touching or even air currents can trigger an episode.
- Neither objective signs of sensory loss nor signs of Vth nerve dysfunction can be demonstrated on examination.

Differential diagnosis

Reactivation of the varicella zoster virus is seen in older people and has predilection for ophthalmic division of the trigeminal nerve.

Treatment

- **First line of treatment: Carbamazepine** (anticonvulsant) to be started with a dose of 100–200 mg/day, increase in 2–3 weeks to 200–400 mg TID.
- **Second line of treatment:** Baclofen, lamotrigine, oxcarbazepine, phenytoin, gabapentin, pregabalin, sodium valproate.
- **Long-acting anesthetic agents:** Localized pain is managed by injecting any of the following into the particular branch of the nerve.
  - Alcohol injection
  - Peripheral glycerol injection
- **Surgery:** Indicated if drug fails or not tolerated.
  - Peripheral neurectomy (nerve avulsion)
  - Open procedures (intracranial procedures)
  - Microvascular decompression
  - Percutaneous rhizotomies
  - Gamma knife radiosurgery: Using stereotactic imaging of the trigeminal nerve root entry zone, radiation to delivered to trigeminal nerve.

VIIth Cranial Nerve: Facial Nerve

Q. AN28.7 Explain the anatomical basis of facial nerve palsy.

FIG. 16.51: Facial nerve anatomy.

Causes of Facial Nerve Palsy

See **Table 16.72**.

Q. List the causes of facial nerve palsy.

TABLE 16.72: Causes of facial nerve palsy.

Unilateral	*Bilateral*
Upper motor neuron ➢ Vascular (stroke) ➢ Tumor ➢ Multiple sclerosis	**Upper motor neuron** ➢ Vascular (multi-infarct dementia) ➢ Motor neuron disease
Lower motor neuron ➢ Bell's palsy ➢ Ramsay Hunt syndrome ➢ Parotid tumor ➢ Head injury ➢ Skull base tumor ➢ Basal meningitis ➢ Diabetes mellitus ➢ Hypertension ➢ Chronic suppurative otitis media	**Lower motor neuron** ➢ Guillain–Barré syndrome ➢ Sarcoidosis (uveoparotid fever) ➢ Leprosy ➢ Lyme disease ➢ Leukemia ➢ Lymphoma ➢ Moebius syndrome ➢ Melkersson–Rosenthal syndrome ➢ Toxin: Thalidomide ➢ Bilateral Bell's palsy

Bell's Palsy

Q. Discuss the etiology, clinical features, differential diagnosis, and management of Bell's palsy.

Q. Write a short essay/note on Bell's palsy.

Most common form of unilateral isolated lower motor neuron type of facial paralysis is Bell's palsy.

Pathophysiology

- Main cause of Bell's palsy is thought to be latent herpes viruses (herpes simplex virus type 1 and herpes zoster virus), which are reactivated from cranial nerve ganglia. It causes **swelling of nerve within** the tight petrous bone **facial canal**.
- Herpes zoster virus shows more aggressive biological behavior than herpes simplex virus type 1.
- Polymerase chain reaction (PCR) techniques have isolated herpes virus DNA from the facial nerve during acute palsy.
- Inflammation of the nerve initially results in a reversible neuropraxia.

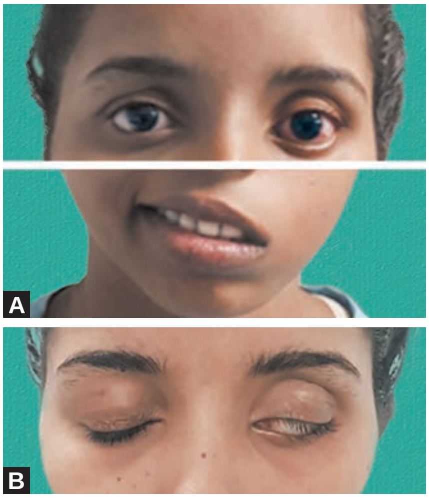
Clinical manifestations

- **Race:** Slightly higher in persons of Japanese descent. Familial incidence—4.1%.
- **Age and gender:** Highest in persons aged 15–45 years. It is rare below the age of 15 and above the age of 60. No gender difference exists.
- **Onset is fairly abrupt, with pain around the ear** preceding the unilateral facial weakness (maximal weakness by 48 hours). Patients often describe the face as "numb" and sometimes give the history of exposure to cold.
- **Associated symptoms:** Hyperacusis, decreased production of tears and saliva, and altered taste, otalgia or aural fullness and facial or retroauricular pain.
- Less common in pregnancy but prognosis is significantly worse in pregnant women.
- **Examination:** Shows features of isolated lower motor neuron facial paralysis. On the affected side **following features are observed**. These include:
    - Paralysis of all the muscles of facial expression **(Fig. 16.52A)**.
    - Dropping of corner of mouth, effacement of creases and skin fold.
    - Involvement of frontalis makes frowning difficult. Eye closure is weak because of involvement of orbicularis oculi
    - Drooling of saliva from angle of mouth.
    - Action of the levator anguli oris on the normal side, makes the angle of mouth to deviate to the opposite side of the lesion, when the patient shows his teeth.
    - When the closure of the eyelid is attempted, the eye on the paralyzed side rolls upward **(Bell's phenomenon) (Fig. 16.52B)**.
    - Due to exposure of the cornea, patient may develop exposure keratitis and corneal ulceration.

Investigations

- No specific confirmatory diagnostic test.
- CSF may show mild lymphocytosis.
- MRI may reveal swelling and uniform enhancement of the geniculate ganglion and facial nerve and in some cases, entrapment of the swollen nerve in the temporal bone.

The differences between upper motor and lower motor neuron facial palsy are presented in **Table 16.73**.



FIGS. 16.52A AND B: Bell's palsy (A) with Bell's phenomenon (B).

The differences between bilateral upper motor and bilateral lower motor neuron facial palsy are presented in **Table 16.74**.

TABLE 16.73: Differences between upper motor neuron (UMN) and lower motor neuron (LMN) facial palsy.

UMN facial palsy	*LMN facial palsy*
➢ Lower part of the face is involved ➢ No Bell's phenomenon ➢ Taste is not affected ➢ No hyperacusis ➢ Usually associated with hemiplegia ➢ Site of the lesion is above facial nucleus usually in the internal capsule ➢ No wasting or atrophy	➢ Both lower and upper part of the face are involved ➢ Bell's phenomenon is seen ➢ Taste is affected ➢ Hyperacusis may be present if nerve to stapedius is involved ➢ Usually not associated unless any pontine lesion is present causing crossed hemiplegia ➢ Usually in the nucleus or distal to the nucleus ➢ Wasting or atrophy may be present

TABLE 16.74: Differences between bilateral upper motor neuron (UMN) and bilateral lower motor neuron (LMN) facial palsy.

Bilateral UMN palsy	*Bilateral LMN palsy*
➢ Emotional fibers—spared ➢ Emotional incontinence present ➢ Associated with bilateral long tract signs ➢ Jaw jerk—exaggerated ➢ Corneal reflex—present ➢ Taste sensation—spared ➢ Gag reflex—exaggerated	➢ Bell's phenomenon present ➢ Emotional fibers—affected ➢ Long tract signs—absent ➢ Jaw jerk—normal ➢ Corneal reflex—absent ➢ Taste sensation—absent

Sequelae of Bell's palsy

- **Incomplete recovery:** Facial asymmetry persists; eye cannot be closed resulting in epiphora. A weak oral sphincter causes drooling and difficulty in taking food.
- **Exposure keratitis:** Eye cannot be closed, tear film from the cornea evaporates causing dryness, exposure keratitis and corneal ulcer.
- **Synkinesis (mass movement):** When the patient wishes to close eye corner of mouth also twitches or vice versa.
- **Tics and spasm:** Result of faulty regeneration of fibers. Involuntary movements are seen on the affected side of face.
- **Contractures:** Results from fibrosis of atrophied or fixed contraction of a group of muscles.
- **Crocodile tears (gustatory lacrimation):** Unilateral lacrimation with mastication. Due to faulty regeneration of parasympathetic fibers which now supply lacrimal gland instead of the salivary glands.
- **Frey's syndrome (gustatory sweating):** Sweating and flushing of skin over the parotid during mastication. It results from parotid surgery.
- Anomalous regeneration of the seventh nerve fibers. Originally connected with the orbicularis oculi come to innervate the orbicularis oris, closure of the lids may cause a retraction of the mouth. Jaw opening causing closure of the eyelids on the side of the facial palsy is termed **Marcus Gunn jaw-winking phenomenon**.

Treatment

- Severe facial weakness may produce inability to blink and lead to exposure keratitis. Use of lubricating eye drops may be needed, and paper tape to close the eye during sleep.
- Massage of weekend muscles.

***Medical treatment of Bell's palsy*:**

- Steroids (Prednisolone) 1 mg/kg/day for 5–7 days and then tapered over the next 1 week.
- Antiviral agents: for 5–7 days.
  - Famciclovir 500 mg BD.
  - Valacyclovir 500 mg BD.
  - Acyclovir 800 mg five times a day.
- Surgical decompression—only if no resolution of symptoms after 2 weeks.

INTRACRANIAL PRESSURE

Q. Discuss the clinical manifestations and management of increased ICP.

Raised Intracranial Pressure

- Normal ICP in adults is <10–15 mm Hg. There are normal regular waves due to pulse and respiration.
- With increased pressure "pressure waves" appear. With continued rise of ICP, the perfusion pressure (PP) falls. When PP falls CBF is reduced. Electrical cortical activity fails if CBF is 20 mL/100 g/min.
- When ICP reaches MAP circulation to the brain stops.
- Raised intracranial pressure (RIP) may be caused by mass lesions, cerebral edema, obstruction to CSF circulation causing hydrocephalus, impaired CSF absorption and cerebral venous obstruction.

Common Causes of Raised Intracranial Pressure

See **Table 16.75.**

TABLE 16.75: Common causes of raised intracranial pressure.

Primary or intracranial causes	
Mass lesions ➢ **Intracranial hemorrhage** (traumatic or spontaneous): Extradural or subdural hematoma, intracerebral hemorrhage ➢ **Brain tumor:** Posterior fossa tumor or high-grade gliomas ➢ **Infective:** Cerebral abscess, tuberculomas, cysticercosis, hydatid cyst ➢ **Colloid cyst** (in ventricles) **Diffuse brain edema or swelling** ➢ Meningoencephalitis ➢ Trauma (diffuse head injury, near-drowning) ➢ Subarachnoid hemorrhage ➢ Metabolic (e.g., water intoxication) ➢ Idiopathic intracranial hypertension ➢ Postneurosurgery	**Disturbance of CSF circulation** ➢ **Obstructive** (noncommunicating) **hydrocephalus:** Obstruction within ventricular system ➢ **Communicating hydrocephalus:** Obstruction outside ventricular system **Obstruction to venous sinuses** ➢ Cerebral venous thrombosis ➢ Trauma (fractures overlying sinuses)
Secondary or extracranial causes	
➢ Hypoxia or hypercarbia (hypoventilation) ➢ Hyperpyrexia ➢ Drug and toxins (e.g., valproate sodium, lead intoxication)	➢ Hepatic failure ➢ Seizure ➢ Reye's syndrome ➢ High-attitude cerebral edema

Clinical Features

- Signs and symptoms of underlying cause.
- **Features of raised ICP (Box 16.68).**
- The speed of increase in the pressure influences presentation.
- **Acute:** If ICP has risen acutely (as in aggressive tumors), there is no time for compensatory mechanisms to develop and causes leading early symptoms, including sudden death. The pulse rate is slower, BP may be elevated (Cushing's reflex) and respiratory depression (Cushing's triad).
- **Slow:** Compensatory mechanisms develop (e.g., alteration in the volume of fluid in CSF spaces and venous sinuses) which minimize symptoms. Raised ICP of more than a few days will result in papilledema.
- **VIth cranial nerve palsy:** Due either to stretching of the long slender nerve or to compression against the petrous temporal bone ridge. It may be unilateral or bilateral.
- **Other cranial nerve** III, V, and VII may also be involved.

Box 16.68: Features of raised intracranial pressure (ICP).

- Diffuse anterior headache worse on lying/straining
- Vomiting
- Diplopia (VIth nerve involvement)
- Papilledema
- Bradycardia, raised blood pressure
- Impaired conscious level: Drowsiness and mental deterioration
- Seizures

Herniation Syndromes

Raised ICT may cause displacement and herniation of the brain. Types of herniation are presented in **Figure 16.53**.

Supratentorial Herniation

- **Uncal:** Most frequent herniation in which downward displacement of the medial temporal lobe (uncus) through the tentorium occurs.
- Results in ipsilateral pupil dilatation, decreased level of consciousness, changes in respiratory patterns, respiratory arrest, and contralateral hemiplegia.
- **Subfalcine** herniation results in opposite lower limb weakness (ACA involvement).

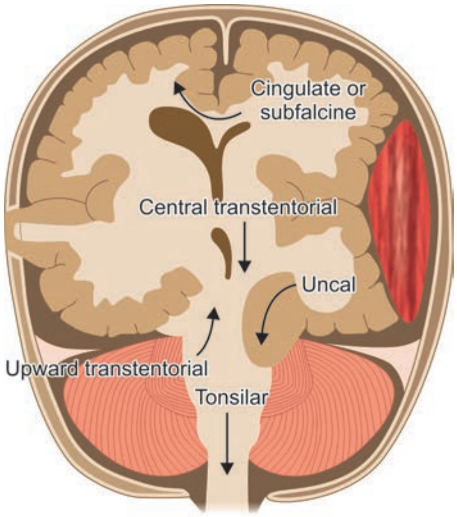


FIG. 16.53: Types of herniation.

Central/Transtentorial Herniation

Results in loss of consciousness, small reactive pupils advancing to fixed/dilated pupils, respiratory changes leading to respiratory arrest and decorticate posturing advancing to flaccidity.

Infratentorial Herniation

Downward herniation of the cerebellar tonsils through the foramen magnum may compress the medulla oblongata (tonsillar coning) causing respiratory and cardiac arrest.

Uncal Syndrome

- Herniation of the temporal lobe (medial) transtentorially results in uncal syndrome.
- It produces drowsiness in early stages and is accompanied by unilateral pupillary dilatation.
- Sometimes due to lateral mass effect, opposite cerebral peduncle is crushed against the tentorium. This causes Babinski sign and weakness of arm and leg ipsilateral to the lesion **(Kernohan–Woltman sign)**.

Investigations

- Depending on the underlying lesion/etiology.
- **CT head:** It may show midline shift and compression of basal cisterns.
- **ICP monitoring:** It is done in selected cases. For example, patients with GCS <8 and CT scan show hematoma, contusion, edema, herniation or compressed basal cisterns.

Q. **Discuss the management of increased ICP.**

Treatment/Management of Increased Intracranial Pressure

Aims (Box 16.69)

- **Airway management**
- Glasgow Coma Scale <8 requires intubation to protect airway.
- **Head positioning:** Head should be kept in midline, with around 15–30° elevation.
- **Temperature control:** Temperature can be lowered with acetaminophen and cooling blankets. Shivering prevented by neuromuscular block.
- **Hemodynamic management:** Maintain MAP >90 mm Hg. Administer normal saline to achieve a central venous pressure of 5–10 mm Hg. Serum sodium to be maintained between 140 and 150 mmol/L.
- **Seizure management:** Prophylactic antiepileptics (phenytoin).
- **Analgesia, sedation and neuromuscular block**
  - *Analgesia:* Opioid like fentanyl and morphine
  - *Sedation:* Benzodiazepines like lorazepam and midazolam
  - *Neuromuscular block:* Pancuronium and vecuronium.

Box 16.69: Aims of management of increased intracranial pressure.

- Relieve the cause (e.g., surgical decompression of mass)
- Steroids to reduce vasogenic edema or shunt
- Procedure to relieve hydrocephalus
- Supportive treatment: Maintenance of fluid balance, blood pressure control, head elevation, and use of diuretics such as mannitol. Intensive care support may be required

Specific Therapy

- **Mannitol:** Osmotic diuretic
  - *Mechanism:* Rheologic and osmotic
  - *Adverse effect:* (1) intravascular volume depletion and (2) acute renal failure
- **Glycerol** acts in a similar fashion but is used less often.
  - Glycerol has caloric value and is beneficial for nutritional support.
  - Renal function does not determine the diuretic action. Hence, it can be given to patients with renal insufficiency.
  - **Side effect:** It has intravascular hemolysis, which can be prevented by giving a low concentration (<20%) at a slow infusion rate (>1 hour).
  - Glycerol is most effective via enteroduodenal administration.
- **Frusemide:** 20 mg 8 hourly.
- **Hypertonic saline:** A more recent treatment for increased ICP is IV administration of 3–23.4% hypertonic saline. IV boluses can reduce ICP and augment CPP for several hours. Creates an osmotic gradient and draws water from the intracellular and extracellular spaces into the intravascular compartment. Potential side effects are listed in **Box 16.70**.
  - The trauma guidelines recommend: Continuous infusion of 3% saline between 0.1 and 1.0 mL/kg/h. Administration on a sliding scale, with the minimal dose needed to maintain ICP <20 mm Hg. Care to be taken while using hypertonic saline to decrease ICP, the osmolarity has to be maintained below 360 mOsm/L.
- **Steroids: Dexamethasone** 4 mg 6 hourly. Helps only in reducing vasogenic edema around tumor, abscess or subdural hematoma. Routine administration of steroids should be avoided in patients with traumatic brain injury and raised ICP.
- **Barbiturate coma in refractory cases:** Pentobarbital 5 mg/kg lowers ICP by lowering the rate of the body's metabolic process, oxygen consumption and carbon dioxide production. Burst suppression correlates with maximal metabolic suppression.

Box 16.70: Side effects of treatment by hypertonic saline in raised ICP.

- Hyperosmolar central pontine myelinolysis
- Congestive heart failure
- Subdural hematomas
- Coagulopathy (rarely)

- **Hyperventilation:** Mechanism by which hyperventilation decreases raised intracranial tension is by decreasing cerebral blood volume by vasoconstriction. Hyperventilation resulting in drop in $PaCO_2$ to around 25–35 decreases CBF.
- **Management of underlying cause** wherever possible or applicable.

Surgical Management

- Management of underlying cause of raised ICP.
- **Mass lesion:** Surgical decompression of mass lesion, removal of space-occupying lesion. Surgical decompression is a life-saving procedure in which limited frontal or temporal lobectomies are done.
- **Hydrocephalus:** Ventriculoatrial or ventriculoperitoneal shunting.

TUMORS OF THE NERVOUS SYSTEM

Among CNS tumors glial tumors are the most common, accounting for 50–60% of primary brain tumors. Meningiomas account for about 25% and schwannomas for about 10%. Few primary tumors are listed in **Box 16.71**.

Cerebellopontine Angle Tumors

Q. Write a short note on cerebellopontine angle (CP angle) tumors.

Cerebellopontine angle is an area of lateral cistern containing CSF, arachnoid tissue, cranial nerves and its associated vessels.

- CP angle tumors constitute the most common posterior fossa tumors and majority of them are benign.
- Various CP angle tumors are listed in **Box 16.72**.

Box 16.71: Few common tumors of CNS.

- Astrocytoma
  - Low-grade astrocytoma
  - High-grade astrocytoma
- Oligodendrogliomas
- Ependymomas
- Medulloblastoma
- CNS lymphoma (more common in HIV patients)
- Meningiomas
- Schwannomas

Box 16.72: Cerebellopontine angle tumors.

- Vestibular schwannoma/ acoustic neuroma
- Meningioma
- Cerebellar glioma

Less likely: Arachnoid cyst, nonacoustic cranial nerve schwannomas, vascular malformations, dermoids, teratomas, and lipomas

Clinical Features

- **Most common:** Progressive unilateral sensory neural hearing loss (SNHL) (retrocochlear) present in 95% of cases and often accompanied by tinnitus which is present in 65% of cases.
- Rare presentations include facial numbness or pain, earache or facial weakness, cerebellar ataxia or symptoms of hydrocephalus (headache, visual disturbance, mental status change, nausea, and vomiting).

Signs

- **Ear:** Normal otoscopy
- **Cranial nerves:**
  - *5th cranial nerve:* Earliest sign is impaired corneal reflex. Motor functions are affected rarely.
  - *7th cranial nerve:* Sensory first; loss of sensation in the posterior superior aspect of external auditory canal (EAC) called Hitselberger's sign. Lower motor neuron facial palsy develops later.
  - *9th and 10th cranial nerve:* Palsy-palatal, pharyngeal and laryngeal paralysis.
- **Eyes:** Nystagmus.
- Cerebellar signs present (ipsilateral).

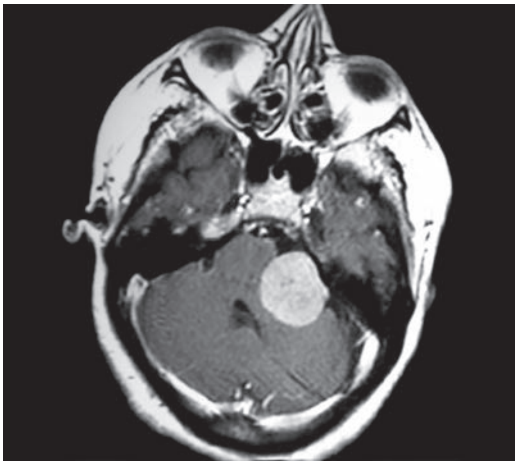

FIG. 16.54: CT showing cerebellopontine angle tumor.

Investigations

- **Audiological tests:** It show features of retrocochlear hearing loss (high-frequency SNHL), recruitment negative, poor speech discrimination score and presence of rollover phenomenon.
- **Acoustic reflex:** Nearly in 75% patients the stapedial reflex is lost.
- **Caloric test:** It is diminished or absent. Normal test finding does not eliminate the diagnosis.
- **Plain X-ray:** The best view is periorbital view; difference of 1 mm in the vertical height of internal acoustic meatus is significant.
- **CT scan (Fig. 16.54):** It cannot detect intermeatal tumors.
- **MRI:** With gadolinium enhancement is gold standard.

Treatment

- Surgical excision
- Radiotherapy: Stereotactic radiosurgery (gamma knife) may stop the growth of vestibular schwannoma mainly in small intracanalicular and extracanalicular lesions.
- Radiosurgery is recommended in bilateral vestibular schwannomas (e.g., Morbus Recklinghausen) but only when the tumors are small.
- Annual imaging is recommended for all patients being managed conservatively for the rest of their life or until vestibular schwannoma growth is seen to a certain limit.

Acoustic Neuroma (Schwannoma)

Q. Write a short note on acoustic neuroma.

- It is a benign tumor which arises from Schwann cells of the 8th cranial (vestibular) nerve. Majority are sporadic and unilateral.
- Common between the 4th and 6th decade of life, with a slight female preponderance.
- **Site:** Commonly arises near the nerve's entry point into the medulla or in the internal auditory meatus and extends into the cerebellopontine angle. Constitutes 80–90% of tumors at the cerebellopontine angle.

Clinical features: Unilateral progressive hearing impairment/loss, sometimes with tinnitus. Large tumors may manifest signs and symptoms of cerebellar and brainstem involvement.

Investigations: MRI is the investigation of choice.

Management: Total surgical excision is the treatment of choice. Stereotactic radiosurgery (radiotherapy) may be used for some tumors.

MISCELLANEOUS

Neuroimaging

Q. Write a short note on radiological investigation used in neurology.

- About 90% of neurological cases can be diagnosed by history alone, with a lesser contribution from examination and investigation.
- Investigations include assessment of structure (imaging) and function (neurophysiology).
- Neurological imaging is used for **assessment of structure**. Various techniques include X-rays (plain X-rays, CT, CT angiography, myelography, and angiography), magnetic resonance (MRI, MRA), and ultrasound (Doppler imaging of blood vessels). However, it is now possible to use imaging techniques to assess CNS function also.
- **Single-photon emission computed tomography** scanning can be used to mark CBF by using a lipid-soluble radioactive tracer. It is useful in dementia or epilepsy. Single photon emission computed tomography (SPECT) is also useful in the **diagnosis of movement disorders** (e.g., by examining dopamine activity to assess the function of the basal ganglia in patients with suspected parkinsonism).

Magnetic Resonance Imaging

Magnetic resonance imaging is an imaging technique used mainly in medical field to produce high-quality images of the inside structures of the human.

The principle of MRI is based on the presence of hydrogen atom in all human tissues. A hydrogen nucleus/atom is a proton whose electrical charge creates a local electrical field. Protons in body tissue are aligned to the magnetic axes. When protons are surrounded by a sudden strong magnetic impulses/field (as in an MRI machine), the protons are aligned along the field. Application of a radiofrequency wave at right angles to their alignment and is imaged. Then the field is suddenly reduced, and the protons resonate and spin, then revert to their normal alignment. When the magnitude and rate of energy release occurs with return to baseline alignment, images are made at different phases of relaxation. They are known as T_1, T_2, T_2 short tau inversion recovery (STIR), Fluid Attenuated Inversion Recovery (Flair), diffusion-weighted imaging (DWI), and other sequences. Recording is done by a coil. These intensities are used to produce images. T_1-weighted sequence accentuates substances that contain fat and T_2-weighted sequence accentuates substances that contain water.

Interpretation: In the brain, T_1-weighted images reveal the nerve connections of white matter and appear white (hyperintense), the congregations of neurons of gray matter appear gray, and cerebrospinal fluid appears dark. These are reversed in T_2-weighted imaging.

Neurological indications for MRI **(Box 16.73)**

Q. Write a short note on neurological indications for MRI.

Box 16.73: Neurological indications for MRI.

MRI is the investigation of choice for the evaluation of all neurological disorders:
- Structural imaging: Produces high-quality soft tissue images. Useful in the investigation of disease of posterior fossa and temporal lobes, inflammatory conditions (e.g., multiple sclerosis), and in investigating epilepsy
- Magnetic resonance angiography (MRA) to study blood vessels in the neck or brain
- Functional MRI: Mainly research tools
- MR spectroscopy: Mainly research tools

Advantages and disadvantages of MRI

See **Table 16.76**.

TABLE 16.76: Advantages and disadvantages of magnetic resonance imaging (MRI).

Advantages	*Disadvantages*
➢ High-quality soft tissue images	➢ Expensive and time consuming
➢ No ionizing radiation involved	➢ Less widely available
➢ Noninvasive	➢ MRA images blood flow, not vessel anatomy
➢ Distinguishes between white and gray matter both in the brain and cord	➢ Spatial resolution not as good as CT
➢ Spinal cord and nerve roots are directly imaged	➢ Requires experienced reader
➢ Pituitary imaging	➢ Not good for evaluation of bone cortex
➢ Resolution superior to CT	➢ Claustrophobic
➢ Useful for demonstration of tumors (posterior fossa and temporal lobes), infarction, hemorrhage, MS plaques, posterior fossa, foramen magnum, and cord. Detailed and accurate evaluation of breast cancers	➢ Less effective than CT in detecting air (lungs) or gas (as in infection or bowel perforation)
➢ MR angiography (MRA) images blood vessels without contrast	➢ Contrast (gadolinium) reactions
➢ Cardiovascular MRI: Gold standard for quantifying ventricular volumes, ejection fraction, and myocardial mass	➢ Contraindications for MRI include: Implanted cardiac pacemakers, vagus nerve stimulators, implanted cardiac defibrillator (ICD), cochlear implants, and deep brain stimulators

Contrast MRI

- Gadolinium is used as intravenous contrast to assess the vascularity in tumors and inflammatory lesions.
- **Side effects:** Headache, nausea, pain and sensation of cold at the injection site, dizziness, and rarely nephrogenic systemic fibrosis (fibrosis of dermis, joints and internal organs including lungs and heart). Contrast (gadolinium) imaging can worsen renal failure, so its best avoided in acute kidney injury (AKI)/chronic kidney disease (CKD).

Special forms of MRI

- Diffusion MRI: To measure the movement or diffusion of extracellular water molecules.
- MR angiography helps us to evaluate intracranial vessels noninvasively to find for aneurysms, stenosis, or malformations.
- Magnetic resonance spectroscopy (MRS)
- Functional MRI to assess blood flow during specific tasks (e.g., speaking, remembering, and calculation).

Complications

MRI is a safe procedure. However, if a metal is present nearby serious injuries may develop when metal gets attracted to strong magnets of MRI and may act like a missile.

X-ray/CT Plain X-rays, CT, CTA

Applications: Radiculography, myelography, intra-arterial angiography
- **X-rays:** For fractures or foreign bodies
- **CT:** First line for stroke
- **Intra-arterial angiography:** Gold standard for vascular lesions.

Advantages: Easily available, relatively economical, and relatively quick.

Ultrasound-Doppler Studies

- Cheap, quick and noninvasive.
- B-mode and color ultrasound are useful in identifying carotid stenosis.

Radioisotope

For establishing the diagnosis, we need to do radioisotope scan, SPECT, and PET.

Q. Discuss the differential diagnosis for "ring-enhancing lesions".

It is abnormal radiological findings observed in MRI or CT scans obtained using radiocontrast. On the image, it appears as an area of decreased density surrounded by a bright rim from concentration of the enhancing contrast dye **(Fig. 16.55)**.

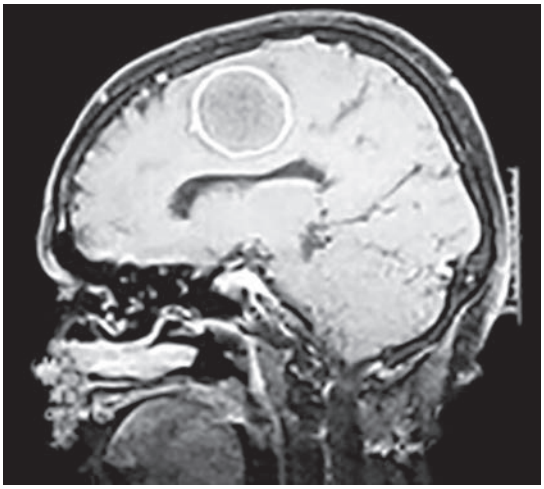

FIG. 16.55: Ring-enhancing lesion on MRI.

Causes for Ring-enhancing Lesions in the Brain

- **Infections:** Early brain abscess, tuberculoma, CNS toxoplasmosis, cysticercosis, fungal infections (nocardiosis, cryptococcosis), neurosyphilis.
- **Inflammatory:** Demyelinating disorders (MS, ADEM), sarcoidosis, Behçet's disease, Whipple's disease.
- **Vascular:** Cerebral venous thrombosis and several other vasculitic disorders.
- **Neoplastic:** Primary (e.g., glioblastoma, low-grade gliomas, CNS lymphoma) and metastasis.

Magnetic Resonance Spectroscopy

Magnetic resonance spectroscopy is a means of noninvasive physiologic imaging of the brain that measures relative levels of various tissue metabolites **(Fig. 16.56)**.

Magnetic resonance spectroscopy patterns in diseases have been shown in **Table 16.77**.

Time of Echo (TE) that conditions the number metabolites

Lactate: Resonates at 1.33 ppm
Lipids: Resonates at 1.3 ppm
Alanine: Resonates at 1.48 ppm
N-acetylaspartate (NAA): Resonates at 2.0 ppm
Glutamine/Glutamate: Resonates at 2.2–2.4 ppm
GABA: Resonates at 2.2–2.4 ppm
2-Hydroxyglutarate: Resonates at 2.25 ppm
Citrate: Resonates 2.6 ppm
Creatine: Resonates at 3.0 ppm
Choline: Resonates at 3.2 ppm
Myo-inositol: Resonates at 3.5 ppm
Glucose: Resonates at 3.43 ppm and 3.8 ppm
Mannitol: Resonates at 3.78 ppm
Water: Resonates at 4.7 ppm

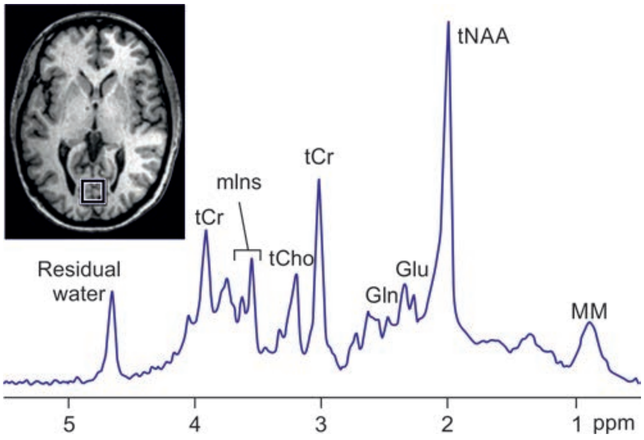

FIG. 16.56: Magnetic resonance spectroscopy of brain.

TABLE 16.77: Magnetic resonance spectroscopy (MRS) patterns of diseases.

Diseases	***MRS patterns***
Glioma	NAA and creatine decrease and choline, lipids, and lactate increase
Radiation effects	NAA, choline and creatine will all be low
Ischemia and infarction	Lactate will increase, later lipid peak appears
Infection	NAA is absent, lactate, alanine, cytosolic acid, and acetate are elevated *Note:* Choline is low or absent in toxoplasmosis, whereas it is elevated in lymphoma, helping to distinguish the two
Progressive multifocal leukoencephalopathy (PML)	Elevated myo-inositol
Canavan disease	Elevated NAA
Hepatic encephalopathy	Markedly reduced myo-inositol and choline. Glutamine is increased
Leigh's syndrome	Elevated choline, reduced NAA

Neurophysiological Testing

Q. Write a short note on electroencephalography.

- **Electroencephalography (Fig. 16.57)**
    - The electroencephalogram recorded from scalp by placing electrodes on the scalp. It is used to detect electrical activity arising in the cerebral cortex. Rhythmic activity is recorded as waves (alpha, beta, gamma, theta, mu, and delta).
    - **Usefulness:**
        - In progressive and continuous disorders such as reduced consciousness, classification and prognosis in epilepsy and diffuse brain diseases [encephalitis, prion (Creutzfeldt–Jakob) diseases and metabolic states (e.g., hypoglycemia, hepatic coma)].
        - Diagnosis of paroxysmal neurological attacks
        - Differentiation between nocturnal epilepsy and parasomnias
        - Diagnosis of psychogenic nonepileptic seizures
        - Characterization of seizure type

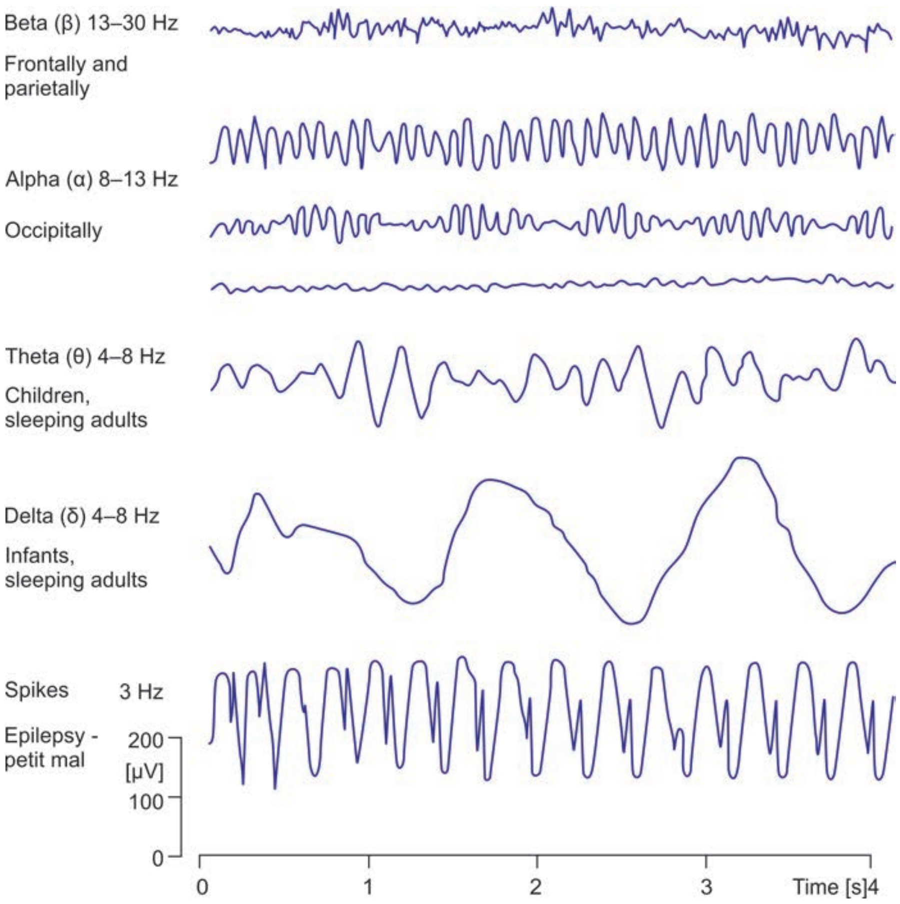

FIG. 16.57: Waves seen in electroencephalography (EEG).

  - Quantification of interictal epileptiform discharge (IED) or seizure frequency
  - Evaluation of candidates for epilepsy surgery.
- **Video EEG:** Useful in definitive diagnosis of epilepsy.
- **Ambulatory EEG** is analog to Holter monitor for cardiac arrhythmias.

Lathyrism

Q. Write a short note on lathyrism.

Lathyrism is a paralyzing disease caused by eating seeds of *Lathyrus sativus* (khesari dal).

Epidemiology

It is prevalent mostly people in India (e.g., Madhya Pradesh, Uttar Pradesh, Bihar and Odisha), Bangladesh, Pakistan, Nepal and Algeria.

Etiology

L. sativus (khesari dal) is a good source of protein. It is relatively cheap pulse and is consumed mostly by the poor agricultural laborer. But it contains L-ODAP (β-N-oxalyl-l-α, β-diaminopropionic acid) also called β-N-oxalylamino-L-alanine, or BOAA, which is an excitatory neurotoxin and glutamate agonist. If the diets containing >30% of this dal is consumed over a period of 2–6 months will produce lathyrism.

Clinical Features

It affects mainly young males between 15 and 45 years of age. In humans, it mainly affects nervous system and is called neurolathyrism which produces pure motor spastic paraplegia. Sensations and sphincters are preserved.

Stages

- **Latent stage:** Patient appears healthy but when subjected to physical stress exhibits ungainly gait. If the disease is recognized at this stage, age, withdrawal of pulse from the diet will result in complete remission of disease.
- **No-stick stage:** During this stage, the patient walks with difficulty having short jerky steps but does not need the aid of a stick.
- **One-stick stage:** The patient walks with a crossed gait with a tendency to walk on toes and develops musculoskeletal stiffness. Use of a stick is necessary to maintain balance.
- **Two-stick stage:** Symptoms are more severe at this stage. Due to excessive bending of the knees and crossed legs, the patient requires support by two crutches for support. The gait is slow and clumsy and complains of easy tiredness after walking a short distance.
- **Crawler stage:** Finally spastic paralysis develops which becomes irreversible. It becomes impossible to maintain erect posture as the knee joints cannot support the weight of the body. The thigh and leg muscles become atrophied and patient crawls by throwing his weight on his hands.

Prevention

- **Vitamin C prophylaxis:** 500–1,000 mg for a week.
- **Banning the crop if possible.**
- **Removal of toxin:**
  - *Steeping method:* Soaking the pulse in hot water for 2 hours and the soaked water is drained off completely. The pulse is washed again with clean water and then drained off and dried in the sun. There will be loss of vitamins and minerals by this method.
  - *Parboiling:* Suitable for large scale operation and is similar to parboiled rice. It destroys trypsin inhibitors.

CHAPTER

17

Toxicology and Envenomation

CLINICAL EXAMINATION OF POISONING CASE

Q. Enumerate the clinical features in general that would help you in diagnosing the poison ingested.

Accidental or intentional poisoning produces a wide range of symptoms and signs. Therefore, meticulous history and physical examination are of paramount importance in recognizing the poisoned patient.

Initial management should be focused on acute stabilization and supportive care till the correct substance is identified.

Various parameters in clinical assessment to determine the type of poisons are listed in **Table 17.1.**

TABLE 17.1: Characteristic features and the type of poisons.

Characteristics	*Type of poisons*
ODOR OF POISON	
Bitter almonds	Cyanide
Acetone	Isopropyl alcohol, methanol, paraldehyde, salicylates
Alcohol	Ethanol
Wintergreen	Methyl salicylate
Garlicky/Garlic like odor	Arsenic, thallium, organophosphates
OCULAR SIGNS	
Miosis	Narcotics (except meperidine), organophosphates, muscarinic mushrooms, clonidine, phenothiazines, chloral hydrate, barbiturates (late), PCP (phencyclidine)
Mydriasis	Atropine, alcohol, cocaine, amphetamines, antihistamines, tricyclic antidepressants (TCAs), cyanide, carbon monoxide
Nystagmus	Phenytoin, barbiturates, ethanol, carbon monoxide
Lacrimation	Organophosphates, irritant gas or vapors
Retinal hyperemia	Methanol
Blurred vision	Methanol, botulism, carbon monoxide
CUTANEOUS SIGNS	
Needle tracks	Heroin, phencyclidine (PCP), amphetamines
Bullae	Carbon monoxide, barbiturates
Dry, hot skin	Anticholinergic agents, botulism
Diaphoresis	Organophosphates, nitrates, muscarinic mushrooms, aspirin, cocaine
Alopecia	Thallium, arsenic, lead, mercury
Erythema	Boric acid, mercury, cyanide, anticholinergics
Cyanosis	Central nervous system (CNS) depressant
ORAL SIGNS	
Salivation	Organophosphates, salicylates, corrosives, strychnine
Dry mouth	Amphetamines, anticholinergics, antihistamine
Burns	Corrosives, oxalate-containing plants
Gum lines	Lead, mercury, arsenic
Dysphagia	Corrosives, botulism

Contd...

Contd...

Characteristics	***Type of poisons***
GASTROINTESTINAL SIGNS	
Cramps	Arsenic, lead, thallium, organophosphates
Epigastric tenderness	Salicylates, nonsteroidal anti-inflammatory drugs (NSAIDs)
Diarrhea	Organophosphates, antimicrobials, arsenic, iron, boric acid
Constipation	Lead, narcotics, botulism
Hematemesis	Aminophylline, corrosives, iron, salicylates
CARDIAC SIGNS	
Tachycardia	Atropine, aspirin, amphetamines, cocaine, cyclic antidepressants, theophylline
Bradycardia	Digitalis, narcotics, mushrooms, clonidine, organophosphates, β-blockers, calcium channel blockers
Hypertension	Amphetamines, LSD (lysergic acid diethylamide), cocaine, PCP
Hypotension	Phenothiazines, barbiturates, TCAs, iron, β-blockers, calcium channel blockers
RESPIRATORY SIGNS	
Bradypnea	Alcohol, narcotics, barbiturates
Tachypnea	Amphetamines, aspirin (salicylates), ethylene glycol, carbon monoxide, cyanide
Pulmonary edema	Hydrocarbons, heroin, organophosphates, aspirin
ARDS	Amphetamine, CO, opiates, irritant gases, TCA, cocaine
NEUROLOGICAL SIGNS	
Ataxia	Alcohol, antidepressants, barbiturates, anticholinergics, phenytoin, narcotics
Coma	Sedatives, narcotics, barbiturates, PCP, organophosphates, salicylates, cyanide, carbon monoxide, cyclic antidepressants, lead
Hyperpyrexia	Anticholinergics, quinine, salicylates, LSD, phenothiazines, amphetamines, cocaine, strychnine, thyroxine
Hypothermia	CNS depressant (opioids, chlorpromazine), alcohol, CO, phenothiazines, hypoglycemics
Muscle fasciculation	Organophosphates, theophylline
Muscle rigidity	Cyclic antidepressants, PCP, phenothiazines, haloperidol
Extrapyramidal signs	Phenothiazines, haloperidol, metoclopramide
Paresthesia	Cocaine, camphor, PCP, MSG (monosodium glutamate)
Peripheral neuropathy	Lead, arsenic, mercury, organophosphates
Altered behavior	LSD, PCP, amphetamines, cocaine, alcohol, anticholinergics, camphor
Seizures	Tricyclic antidepressants, isoniazid, selective serotonin reuptake inhibitors (SSRIs)
Tremors	Beta--agonist, alcohol, lithium, phenytoin, mercury, arsenic
METABOLIC SIGNS	
Metabolic acidosis	Cyanide, ethylene glycol, metformin, methanol, salicylates, iron, isoniazid
Elevated osmolal gap	Ethanol, isopropanol, methanol, ethylene glycol, isoniazid
ECG CHANGES IN COMMON POISON	
Narrow QRS tachycardia	Amphetamines Anticholinergic drugs Theophylline
Wide QRS tachycardia	Antihistamines Cocaine Propoxyphene Sodium channel blockers Tricyclic antidepressants
Bradycardia with narrow QRS	α-adrenergic blockers β-blockers Calcium channel blockers Cardiac glycosides Class Ia antiarrhythmics Sodium channel blockers
Bradycardia with wide QRS	β-blockers Calcium channel blockers
QT interval prolongation	Antihistamines Antipsychotics Class Ia antiarrhythmics Sotalol Tricyclic antidepressants

Contd...

Contd...

Characteristics	***Type of poisons***
	Erythromycin Fluoroquinolones Halofantrine Hydroxychloroquine
RADIOPAQUE POISONS	
Radiopaque on plain X-ray (**CHIPES**—acronym)	**C**—Calcium, chlorinated compounds **H**—Heavy metals (iron, mercury, etc.) **I**—Iodinated compounds (thyroxine) **P**—Psychotropics, potassium salts, packers (cocaine/opium) **E**—Enteric-coated drugs like aspirin **S**—Salicylates

(ARDS: Acute respiratory distress syndrome; CO: Carbon monoxide)

TOXIDROMES (TABLE 17.2)

Q. List the common toxidromes that are commonly encountered in clinical practice.

Q. FM8.7 Describe simple bedside clinic tests to detect poison/drug in a patient.

Based on history and clinical findings, it may be possible to define a syndrome associated with certain poisons. This is called toxidrome/toxic syndrome.

TABLE 17.2: Various toxidrome and related findings.

Toxidrome	***Vital signs***	***Mental status***	***Pupils***	***Other findings***	***Examples***
Anticholinergic **(Fig. 17.1)**	Hyperthermia, tachycardia, hypertension, tachypnea	Agitated, hallucinating	Mydriasis	Dry flushed skin, urinary retention	Antihistamines, TCAs, atropine, scopolamine, antispasmodics, trihexyphenidyl
Cholinergic **(Fig. 17.2)**	Bradycardia (muscarinic), tachycardia and hypertension (nicotinic)	Confused, coma	Miosis	**Fasciculations SLUDGE** (**S**alivation, **L**acrimation, **U**rination, **D**iarrhea, **G**I upset, **E**mesis)	Organophosphate pesticides, nerve agents—physostigmine
Hallucinogen	Hyperthermia, tachycardia, hypertension	Hallucination, synesthesia, agitation	Mydriasis	Nystagmus	PCP (phencyclidine), LSD (lysergic acid diethylamide), mescaline
Opioid	Hypothermia, bradycardia, hypotension, bradypnea	CNS depression, coma	Miosis	Hyporeflexia, pulmonary edema	Opioids (heroin, morphine, methadone, hydromorphone, etc.)
Sedative-hypnotic	Hypothermia, bradycardia, hypotension, bradypnea	CNS depression, confusion, coma	Miosis	Hyporeflexia	Benzodiazepines, barbiturates, zolpidem, alcohols
Serotonin syndrome **(Fig. 17.3)**	Hyperthermia, tachycardia, hypertension, tachypnea	Confused, agitated coma	Mydriasis	Tremor, myoclonus, diaphoresis, hyperreflexia, trismus, rigidity	MAOIs, SSRIs, meperidine, dextromethorphan
Sympathomimetic **(Fig. 17.4)**	Hyperthermia, tachycardia, tachypnea	Agitated, hyperalert, paranoia	Mydriasis	Diaphoresis, tremors, hyperreflexia, seizures	Cocaine, theophylline amphetamines, pseudoephedrine

(MAOIs: Monoamine oxidase inhibitors; SSRIs: Selective serotonin reuptake inhibitors or serotonin specific reuptake inhibitors ; TCAs: Tricyclic antidepressants)

Management of Patient with Poisoning

Q. IM21.1 Describe the initial approach to the stabilization of the patient who presents with poisoning.

Q. FM8.8 Describe basic methodologies in treatment of poisoning: decontamination, supportive therapy, antidote therapy, procedures of enhanced elimination.

Management/Treatment

Goals of Treatment

These include: (A) Support vital signs, (B) Diagnostic testing, (C) Reduce absorption of the toxin, (D) Enhancement of poison elimination, and (E) Neutralize toxin.

FIG. 17.4: Sympathomimetic toxidrome.

In the poisoned patient, diagnostic evaluation and therapeutic interventions often are initiated simultaneously.

A. Supportive Care

Patients who are seriously poisoned must receive early appropriate management. Outcome depends on appropriate nursing and supportive care, and on appropriate treatment of complications. The aims are:

- To **maintain physiologic homeostasis** till poison is eliminated from the body and the patient resumes normal physiological functions. As with any unstable or critically ill patient, the resuscitation [airway, breathing, circulation (ABC)] with basic life support takes priority.
- To **prevent and treat secondary complications:** Supportive therapy for central nervous system (e.g., cerebral edema), cardiopulmonary system (e.g., pulmonary edema, pneumonia), and renal system with proper care for coma, seizures, hypotension, bedsores, arrhythmias, sepsis, thromboembolic disease, coagulopathy, hypoxia, and acute renal failure.

B. Diagnostic Testing

General tests

- Complete blood count
- Serum electrolytes, blood urea nitrogen (BUN), and creatinine
- Liver function test
- Arterial blood gas
- Electrocardiogram
- Urine pregnancy test in all women of childbearing age
- Radiographic studies—radiopaque poisons listed in **Table 17.1**

Specific tests

Measurement of drug or toxin concentrations in body fluids (blood, urine, lavage fluid)

C. Reduce Absorption of the Toxin

- **Inhalational exposure:** Evacuation from toxic environment and provision of supplemental oxygen.
- **Dermal exposure:** Removal of contaminated clothing and shower or irrigation of affected site (dust before shower for dry chemical).
- **For eye exposure:** Removal of chemicals by copious irrigation of the affected eye by up to 1 L of saline or symptomatic improvement occurs.
- **Oral exposure:** Inducing emesis, performing gastric lavage, activated charcoal **(Box 17.1)**, whole bowel irrigation, cathartics.

Gastric decontamination

- **Emesis induction:** Forced emesis, if patient is awake (using saline, ipecac).
- **Gastric lavage** should be considered for life-threatening poisons that cannot be treated effectively with other therapies.
  - **Time of lavage:** Gastric lavage decreases absorption by 42% if done 20 minutes and by 16% if performed at 60 minutes.
  - **Method:** Performed by first aspirating the stomach and then repetitively instilling and aspirating fluid. Choice of fluid is tap water—5–10 mL/kg. Left lateral position better and delays spontaneous absorption.
  - **Contraindication:** Unprotected airway, comatose patients, corrosive poisoning, kerosene (hydrocarbons) poison, and in patients with convulsions.
  - Toxins adsorbed by activated charcoal **(Box 17.1)**.
- **Activated charcoal administration:** 25–100 g activated charcoal mixed with water to form a slurry should be administered at a rate of not less than 12.5 g/h through nasogastric tube.

Box 17.1: Adsorption of toxins to activated charcoal.

Well adsorbed		*Moderately adsorbed*	*Poorly adsorbed*
Aflatoxins	Cimetidine	Antidiabetic drugs	Alcohols
Amphetamines	Dapsone	Kerosene	Carbamates
Antidepressants	Digitalis	Paracetamol	Corrosives
Antiepileptics	NSAIDs	Phenol	Cyanide
Antihistamines	Opiates	Salicylates	Ethylene glycol
Atropine	Phenothiazines		Heavy metals
Barbiturates	Quinine, Quinidine		Hydrocarbons
Benzodiazepines	Strychnine		Organophosphates
Beta blockers	Tetracycline		
Chloroquine	Theophyline		

- **Multidose activated charcoal** at a rate of at least 12.5 g/h is useful in poisoning with carbamazepine, dapsone, phenobarbital, quinine, theophylline, and phenytoin.
- **Fuller's earth** (2 g/kg in water; maximum 150 g in water) be given as soon as possible per oral or via a nasogastric tube.
- **Cathartics:** Sorbitol, magnesium citrate, magnesium sulfate, sodium sulfate as cathartics for patients who have ingested materials that are absorbed slowly.
- **Dilution—milk/other drinks:** Advised only after the ingestion of corrosives (acids, alkali). **Whole bowel irrigation:** 1,500–2,000 mL/h through a nasogastric tube. It is performed by administering a bowel-cleansing solution containing electrolytes and polyethylene glycol by gastric tube. It may be used for potentially toxic ingestions of sustained-release or enteric-coated drugs or to remove illicit drug. Contraindications are GI hemorrhage, ileus, and hemodynamic instability.
- **Endoscopic or surgical removal** of ingested substance may be useful in rare situations (e.g., ingestion of a potentially toxic foreign body that fails to transit the gastrointestinal tract).

D. Enhance of Poison Elimination

- **Indications:** Increased elimination is possible only if
  - Drug is distributed predominantly in the ECF (extracellular fluid) and drugs that have a low protein binding.
- **Methods:** Keep a good urine output 150–200 mL/h.
  - **Alkalinization of urine using sodium bicarbonate to produce urine with a pH ≥7.5:** For salicylate, methotrexate, and phenobarbital poisoning.
  - **Extracorporeal removal:**
    - **Hemodialysis:** For lithium, barbiturates, salicylates, acetaminophen, valproate, alcohols, glycols.
    - **Hemoperfusion:** For theophylline, digitalis, paraquat, lipid-soluble drugs (aminoglycosides, vancomycin, and metal chelate complexes).
  - **Exchange transfusion:** Useful in cases of massive hemolysis, severe methemoglobinemia or sulfhemoglobinemia.

E. Neutralize Toxin

Antidotes may prevent absorption, bind and neutralize poisons directly, antagonize end-organ effects, or inhibit conversion to more toxic metabolites **(Table 17.3).**

Q. Write a short note on antidote.

Neutralize toxins/poisons by toxin-specific antidotes **(Table 17.3).**

TABLE 17.3: Toxin-specific antidotes.

Toxin/poison	*Specific antidote*	*Toxin/poison*	*Specific antidote*
Acetaminophen	N-acetylcysteine	Methanol	Ethanol, fomepizole
Anticholinergics	Physostigmine	Methemoglobinemia	Methylene blue
Benzodiazepines	Flumazenil	Glycol	Ethanol, fomepizole
Beta-blockers	Glucagon	Opioid	Naloxone
	Calcium	Oral hypoglycemics	Glucose
	Insulin + dextrose/lipid emulsion therapy	Organophosphate	Atropine/2-PAM (pralidoxime)
Calcium channel blockers	Glucagon		
	Insulin + dextrose *(hyperinsulinemia euglycemia therapy)*	Snakebites	Snake antivenom
	Calcium/lipid emulsion therapy	Sulfonylurea	Octreotide + dextrose
Carbamate	Atropine	Tricyclic antidepressants	Sodium bicarbonate
Carbone monoxide	Hyperbaric oxygen	Warfarin	Vitamin K
		Dabigatran	Idarucizumab
		Copper	Penicillamine, dimercaprol, Ca-EDTA
Cyanide	Amyl nitrite pearls Sodium nitrite (3% solution) Sodium thiosulfate (25%)	Iron	Desferrioxamine
		Lead	Ca-EDTA, dimercaprol, British anti-Lewisite (BAL)
		Mercury	DMPS (2,3-dimercapto-1-propanesulfonic acid), DMSA (meso-2, 3-dimercaptosuccinic acid), BAL
Digoxin	Digoxin antibodies	Arsenic	BAL and derivatives
Heparin	Protamine sulfate	Antimony	BAL and derivatives
Isoniazid	Pyridoxine	Botulism	Botulinum antitoxin
Datura	Physostigmine	Methemoglobinemia-causing agents (copper, nitrates, dapsone)	Methylene blue

INSECTICIDE POISONING

Q. PH1.52 **Discuss the clinical manifestations, diagnosis, complications, and management of organophosphorus and carbamate poisoning.**

Organophosphate and Carbamate Poisoning

Organophosphorus (OP) compounds are widely used as pesticides in developing countries and are a common cause of poisoning.

Classification of Organophosphate and Carbamate (Box 17.2)

Mode of intoxication: It may occur through ingestion, inhalation or dermal absorption.

Mechanism of OP Toxicity (Fig. 17.5)

- OP compounds irreversibly bind to serine-OH group at the active site of acetylcholinesterase (AChE) and phosphorylate. This inactivates the enzyme AChE. It leads to the accumulation of acetylcholine (ACh) in cholinergic synapses.
- Spontaneous hydrolysis of the OP-enzyme complex allows reactivation of the enzyme. However, loss of a chemical group from the OP-enzyme complex prevents further enzyme reactivation, a process known as **"aging"**. Aging is characterized by loss of alkyl group + strengthening of covalent bond.
- Phosphorylated AChE is very stable. Inhibition of enzyme activity → accumulation of ACh in the synapse and neuromuscular junction (NMJ). It causes overstimulation of cholinergic receptors. After aging has taken place; new enzyme needs to be synthesized before function can be restored.

Box 17.2: Classification of organophosphate and carbamate.

- **Organophosphorus**
  - *Diethyl organophosphorus*: Quinalphos, chlorpyriphos, diazinon, triazophos, phorate, dimethoate, parathion-ethyl
  - *Dimethyl organophosphorus*: Monocrotophos, dichlorvos, acephate, malathion, fenthion, methamidophos and phosphamidon
- **Carbamate:** Methomyl
- **Organochloride:** Endosulfan, endrin
- **Pyrethroids:** Cypermethrin, alpha-cypermethrin, deltamethrin, cyhalothrin
- **Neonicotinoid:** Imidacloprid, acetamiprid

FIG. 17.5: Mechanism of organophosphorus poisoning.

Clinical Course after Acute Poisoning (Table 17.4)

Q. Write a short essay/note on clinical signs of organophosphorus poisoning.

TABLE 17.4: Clinical course after acute organophosphorus poisoning.

Time of manifestation	***Mechanism***	***Manifestation***
Acute (minutes to 24 hours): Acute cholinergic syndrome	Nicotinic receptor action	*Musculoskeletal:* Weakness, fasciculations, cramps, paralysis
		Cardiovascular: Tachycardia, hypertension
	Muscarinic receptor action	*Gastrointestinal:* Increased salivation, nausea, vomiting, abdominal pain, diarrhea, fecal incontinence *Genitourinary:* Urinary incontinence *Cardiovascular:* Bradycardia (80%), hypotension *Respiratory:* Rhinorrhea, stridor, bronchospasm, bronchorrhea, cough *Ocular:* Lacrimation, miosis
		Skin: Flushing, diaphoresis, cyanosis
	Central receptors	Anxiety, restless, convulsions, insomnia, tremors, respiratory depression
Delayed (24 hours to 2 weeks): Intermediate syndrome	Nicotinic receptor action	Proximal muscle weakness, hyporeflexia, bulbar weakness
	Muscarinic receptor action	Bradycardia, miosis, salivation
	Central receptors	Coma, extrapyramidal manifestation
Late (beyond 2 weeks): Delayed polyneuropathy	Peripheral neuropathy target esterase	Peripheral neuropathy

Triphasic Illness

1. Acute cholinergic syndrome
    - **Onset:** Cholinergic symptoms within first 24 hours.
    - **Features (Table 17.4)**
    - SLUDGE = Salivation, Lacrimation, Urination, Defecation, Gastric Emptying
    - BBB = Bradycardia, Bronchorrhea, Bronchospasm
2. Intermediate syndrome
    - **Onset:** 24–96 hours after poisoning, after the cholinergic phase settles, seen in 10–40% of cases.
    - **Mechanism:** Excess Ach at NMJ causes downregulation of nicotinic receptors and muscles affected.
    - **Features:** Characterized by proximal neck muscle weakness, decreased deep tendon reflexes (DTRs), cranial nerve abnormalities (bulbar), and respiratory insufficiency
    - **Duration:** Lasts for few days to about 3 weeks.
3. OP-induced delayed polyneuropathy (OPIDN)
    - **Onset:** 1–3 weeks after acute exposure.
    - **Mechanism:** Due to degeneration of long myelinated nerve fibers. Pure motor or sensor-motor.
    - **Features:** Characterized by cramps in the legs, numbness and paresthesia in the distal upper and lower limbs, shuffling gait, foot and wrist drop. Other features are wasting, DTR reduced/absent.
    - **Recovery is incomplete.**

Q. FM9.5 Describe general principles and basic methodologies in treatment of poisoning: decontamination, supportive therapy, antidote therapy, procedures of enhanced elimination with regard to organophosphate poisoning.

Diagnosis of Organophosphate Poisoning

- **Clinical diagnosis:** Dreisbach's severity of OP poisoning is presented in **Table 17.5**.
- **Laboratory:**
    - Red cell cholinesterase
    - Plasma [Pseudo, Butyryl (Bu)] cholinesterase
    - *Electrocardiogram (ECG):* The most common ECG abnormality was prolonged QTc and sinus tachycardia.
    - *Arterial blood gas (ABG):* Hypoxemia.

TABLE 17.5: Dreisbach's classification showing severity of poisoning.

Grade	*Symptoms*
Mild	Nausea
Moderate	Lacrimation, salivation, miosis, fasciculation
Severe	Incontinence, apneic spells, ARDS, areflexia, seizures, coma

(ARDS: Acute respiratory distress syndrome)

Management of Organophosphate

Acute Cholinergic Syndrome

Steps

- Assess and record 15-point Glasgow Coma Scale (GCS).
- Measure pulse rate and blood pressure and auscultate the lungs.
- Make patients to lie down in the left lateral position—with head lower than the feet.
- Start oxygen.
- Intubate, if the patient has a respiratory distress. Start atropine quickly to reduce bronchorrhea responsible for respiratory distress.
- Set-up an infusion of 0.9% normal saline. Aim at systolic blood pressure >80 mm Hg and urine output >30 mL/h.
- Remove the contaminated clothes and thoroughly wash the skin with soap and water.
- Perform gastric decontamination with gastric lavage once the patient is stabilized and within 2 hours of ingestion. Skin exposure would require irrigation of the skin with copious amounts of water and liberal use of soap. Eye exposure should be irrigated with copious amount of normal saline.
- Give activated charcoal (50 g in 200 mL) (not much benefit due to rapid absorption of poison into blood).

Drugs Used

1. **Atropine**
    – Early use of sufficient doses of atropine is **lifesaving in patients with severe toxicity.** It reverses ACh-induced bronchospasm, bronchorrhea, bradycardia, and hypotension.
    – **When the diagnosis is uncertain:**
        - **Atropine challenge test:** To be performed, if not sure that the patient has consumed OP.
        - **Inject 0.6–1 mg IV atropine:** If pulse rate goes up by 25/minute or skin flushing develops, patient has mild or no toxicity or OP poisoning is unlikely.

Dose and mode of administration of atropine

- **Bolus**
  - Inject 1.8–3 mg (3–5 mL) of atropine bolus.
  - *Check three things after 5 minutes:* Pulse, blood pressure, and chest crepitations.
  - Aim for heart rate > 80 beats/minute, SBP > 80 mm Hg, and a clear chest.
  - If the above-mentioned objectives are not achieved, double the atropine dose every 5 minutes.
  - Review patient every 5 minutes. Once these parameters start improving, repeat last same or smaller dose of atropine. If there is persistent and satisfactory improvement in these parameters after 5 minutes, atropine infusion can be planned.
- **Atropine infusion**
  - Calculate total dose of atropine required for rapid atropinization.
  - Start hourly atropine infusion at 10–20% of total dose of atropine required for atropinization.
  - Most patients do not need > 3–5 mg/h of atropine infusion.
  - Use three-point checklist **(secretions, heart rate, pupils)** to reduce infusion rate by 20% every 4 hourly once the patient is stable. Target endpoints for atropine infusion are presented in **Box 17.3**.
  - Bronchorrhea is the most important sign for titrating dose of atropine once patient is stable.
- **Atropine toxicity = absent bowel sounds + fever + confusion/delirium**
  - Stop atropine infusion for 60 minutes, if patient has developed atropine toxicity. Restart infusion at lower rate, once the temperature comes down and the patient gets calm. If atropine is contraindicated, glycopyrrolate can be used for bronchorrhea. **Glycopyrronium bromide** can be an alternative for peripheral symptoms (0.2 mg IM stat repeated 6 hourly).

Q. Write a short essay/note on pralidoxime (2-PAM).

2. **Pralidoxime (2-PAM):** Pralidoxime reactivates acetylcholinesterase enzymes by removing the phosphoryl group deposited by the organophosphate.
   - Only to treat organophosphorus poisoned patients.
   - *Bolus dose:* 30 mg/kg (i.e., 1–2 g for adults) in 100 mL normal saline over 15–30 minutes.
   - *Maintenance dose:* Continuous infusion of 8–12 mg/kg/h.
   - PAM must be given by infusion. Go slow, both for bolus and maintenance. A fast infusion can cause vomiting, hypertension, cardiac arrhythmia or a cardiac arrest.
   - Give PAM until atropine is no longer required.

   Benzodiazepines
   - *Agitation and seizures:* Diazepam 10 mg slow IV push, repeated as necessary. Up to 30–40 mg diazepam per 24 hours can be given.
3. **Supportive measures**
   - Mechanical ventilation, vasopressors, antibiotics, diuretics (if pulmonary edema), early enteral feeding, physiotherapy.

Chronic Organophosphate Poisoning

Clinical features

- Delayed polyneuropathy (OPIDN)
- Neuropsychiatric disorder

Triorthocresyl phosphate (TOCP) poisoning associated polyneuropathy also called as **Ginger Jake Paralysis.** Owing to the consumption of ginger which was used in manufacture of bootleg alcohol and was adulterated with TOCP. It usually manifests after about 10–20 days causes distal predominant neuropathy.

Diagnosis: Clinical diagnosis, by suspicious and exclusion.

Box 17.3: Target endpoints for atropine infusion.

- Clear chest on auscultation
- Heart rate > 80 beats/minute (WHO recommends > 100 bpm)
- Systolic BP >80 mm Hg
- Pupils no longer pinpoint
- Dry axillae

Treatment: Not established. Only supportive measures.

Carbamates

Q. Discuss management of carbamate poisoning.

- Examples: Sevin, Baygon, Lannate, carbaryl, aldicarb.
- Medicinal forms include physostigmine, pyridostigmine, and neostigmine.
- Cholinesterase inhibitors that are **structurally related to organophosphates.** Transiently and reversibly inhibit cholinesterase (<6 h). Regeneration of enzyme occurs within minutes to hours; therefore, aging does not occur.

- **Symptoms** of intoxication are similar to organophosphates, but are of shorter duration.
- Carbamates do not effectively penetrate into CNS, so **less central toxicity** and no seizures.
- Atropine therapy usually not needed for longer than 6–12 hours.
- **Avoid pralidoxime (2-PAM):** Since irreversible binding does not occur, it is not needed, and potentially can worsen some carbamate poisonings.

Organochlorine Poisoning

Q. Write a short essay on organochlorine poisoning.

Classification of Organochlorine (Box 17.4)

Box 17.4: Classification of organochlorine.

Dichlorodiphenylmethane: DDT, methoxychlor
Hexachlorocyclohexane: Lindane
Cyclodienes
- Aldrin, chlordane, dieldrin
- Endrin, endosulfan, heptachlor
- Chlordecone (kepone): Mirex

Acute organochlorine poisoning

- *Prodromal symptoms:* Tremor, ataxia, myoclonus, dizziness, confusion, paresthesia of mouth, nausea, vomiting.
- *Typical presentation:* **Status epilepticus** followed by respiratory failure, cardiac arrhythmias, rhabdomyolysis, and acute renal failure.

Treatment

- **Control seizure:** The same way as "status epilepticus": Benzodiazepines, phenobarbital, phenytoin.
- Prevent complications.

Subacute Organochlorine Poisoning

- **Hyperexcitability stage:** Tachycardia, tremor, hyperreflexia.
- **Treatment**
  - **Symptomatic treatment:** Anxiolytic
  - **Enhance elimination:** Cholestyramine.

Chronic Organochlorine Poisoning

- Organochlorine insecticides interfere with endocrine and reproductive systems.
- Individuals who work with the insecticides show low sperm count and motility, infertility, and abortion.
- The insecticides can be carcinogenic to animals.

Paraquat Poisoning

- Paraquat is a common herbicidal poison with very high case fatality (>50%).
- The toxicity is related to generation oxygen species which cause cellular damage via lipid peroxidation, activation of NF-kB, mitochondrial damage, and apoptosis.
- Ingestion of large amounts results in fulminant organ failure: pulmonary edema, cardiac, renal and hepatic failure.
- Smaller quantities mainly damage the lung and kidney. Acute kidney injury sets in rapidly. The lung involvement occurs in two phases: an acute alveolitis that occurs within 1–3 days followed by a secondary fibrosis. Severe mucosal erosions with bleeding are seen in the GIT and acute hepatitis are seen.
- There is no specific antidote available. Activated charcoal and Fuller's earth can minimize further absorption. Gastric lavage is contraindicated.
- Treatment is supportive, oxygen supplementation and nutritional support.
- Hemodialysis and hemoperfusion are initiated for renal failure.
- Immunosuppression with cyclophosphamide, MESNA, methylprednisolone and dexamethasone have been used to prevent fibrosis. Antioxidants like vitamins C and E, N-acetylcysteine, desferrioxamine, salicylic acid have also been tried.

SNAKEBITE/OPHITOXEMIA

Q. IM20.1 Enumerate the local poisonous snakes and describe the distinguishing marks of each.

Q. IM20.4 Elicit and document and present an appropriate history, the circumstance, time, kind of snake, evolution of symptoms in a patient with snake bite.

Classification of Poisonous Snakes (Box 17.5)

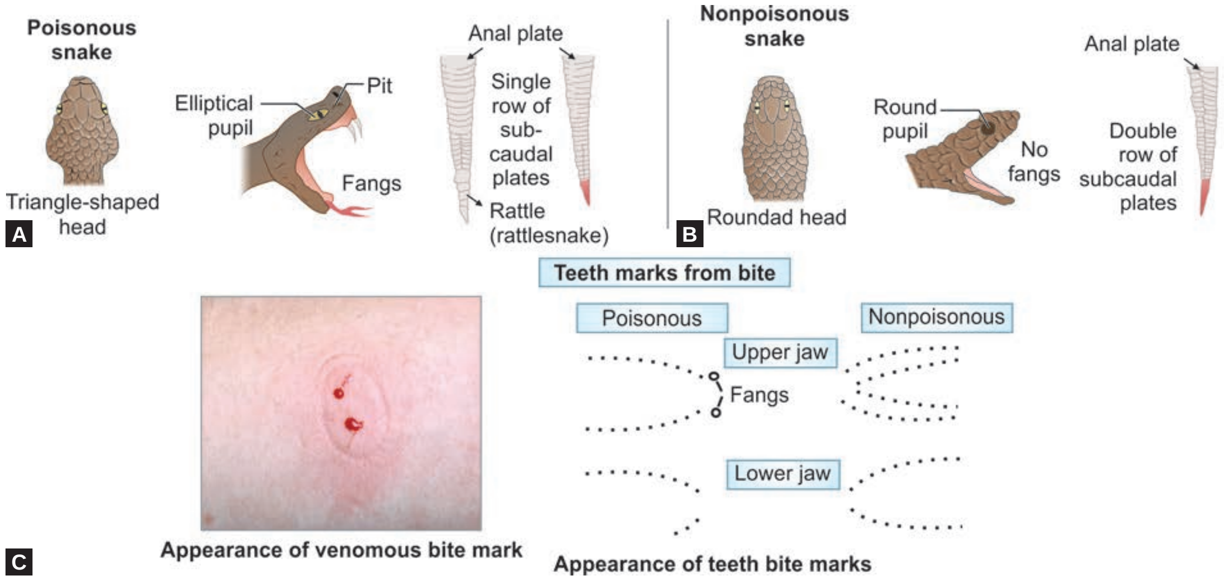
India recorded a staggering 1.2 million snakebite deaths in the 20-year period from 2000 to 2019 with an average of 58,000 deaths caused by snakebite annually. Around 70% of these deaths occurred in limited, low altitude, rural areas of eight states—

Box 17.5: Classification of poisonous snakes.

1. **Elapidae (neurotoxic):** Examples:
   - Common cobra/*nag* or kalsap or *Naja naja*
   - King cobra: *Raj nag* or *Naja hannah* or *Naja bungarus*
   - Krait: Subgrouped into: (a) common krait or *Bungarus caeruleus*; (b) banded krait or *Bungarus fasciatus*; (c) coral snake; (d) tiger snake; (e) mambas and (f) death adder.
2. **Viperidae (vasculotoxic):** They are grouped into:
   - **Pitless vipers:** These include: (a) Russell's viper and (b) saw-scaled viper
   - **Pit vipers:** These include: (a) pit viper—crotalidae and (b) common green pit viper.
3. **Hydrophidae (myotoxic):** About 20 types of sea snakes are found in India. All are poisonous.

TABLE 17.6: Various components of snake venom and their actions.

Component	*Action*
Serine proteases	Hemolysis
Other proteases	Hemolysis
Phospholipase A2	Myotoxic, cardiotoxic, neurotoxic, increases vascular permeability
Hyaluronidase	Local tissue destruction
Neurotoxin ➢ Alpha-bungarotoxin, cobrotoxin ➢ Beta-bungarotoxin, crotoxin	 ➢ Postsynaptic inhibition ➢ Presynaptic inhibition



Poisonous snake
Triangle-shaped head
A
Elliptical pupil
Pit
Fangs
Anal plate
Single row of sub-caudal plates
Rattle (rattlesnake)
Nonpoisonous snake
Roundad head
B
Round pupil
No fangs
Anal plate
Double row of subcaudal plates
C
Appearance of venomous bite mark
Teeth marks from bite
Poisonous
Nonpoisonous
Upper jaw
Fangs
Lower jaw
Appearance of teeth bite marks

FIGS. 17.6A TO C: (A and B) Differences between poisonous and nonpoisonous snakes; (C) Teeth marks from bite.

Bihar, Jharkhand, Madhya Pradesh, Odisha, Uttar Pradesh, Andhra Pradesh (including Telangana), Rajasthan, and Gujarat. Snake may be venomous or nonvenomous. When a venomous snakebites, it may excrete venom. **Snake venom** is a **toxin (hematotoxin, neurotoxin, or cytotoxin). Composition of snake venom is mentioned in Table 17.6.**

Teeth bite marks difference between poisonous and nonpoisonous snakes **(Fig. 17.6C)**.

- **Poisonous:** Two fang marks with or without marks of outer teeth.
- **Nonpoisonous:** Two fang marks with number of small teeth marks.
- Differences between poisonous and nonpoisonous snakes are described in **Figures 17.6A** and **B** and **Table 17.7**.

TABLE 17.7: Differences between poisonous and nonpoisonous snakes.

Points	*Poisonous snakes*	*Nonpoisonous snakes*
1. Belly scales	*Large:* They cover the entire breadth of belly	*Small:* They never cover
2. Head scales	➢ Usually small in vipers ➢ May be large in pit vipers ➢ Cobras and Coral snakes where third labial touches the eye and nasal shields ➢ Kraits, where there is no pit and the third labial does not touch the nose and eye	Are usually large with exceptions as outlined under poisonous snakes
3. Fangs	Are hollow-like hypodermic needle	Short and solid
4. Tail	Compressed	Not markedly compressed
5. Habits	Usually nocturnal	Not so
6. Teeth bite marks	Two fang marks with or without marks of other teeth	Two fang marks with number of small teeth marks

Clinical Feature of Snakebite

Q. Discuss:

- Clinical features of poisonous snakebite.
- Cobra bite envenomation—features and treatment.

FEATURES OF COMMON SNAKES SEEN IN INDIA

Common Cobra	➢ Zoological name: *Naza naza* ➢ Common name: Common cobra, Nag ➢ Common cobras are usually brown or black in color ➢ Head is covered with shields. The third supralabial shield touches the eye and nose ➢ A small wedge-shaped scale called as cuneate is present between 4th and 5th infralabials ➢ Pupils are round ➢ Hood is present. Dorsal aspect of hood may have monocellate (monocle) or binocellate (spectacle) mark. Ventral surface of hood have two dark spots ➢ Fangs are short, grooved and situated anteriorly ➢ Tail is cylindrical. Caudal scales (scales on undersurface of tail) are divided and double ➢ Venom—neurotoxic	Indian Krait	➢ Zoological name: *Bungarus caeruleus* ➢ Common name: Indian krait, common krait, Blue krait, Maniyar, Kawadya ➢ Usually steel blue or black in color with single or paired white bands on back. The bands are more distinct towards the tail. ➢ Pupils are round. ➢ Large hexagonal scale presents over back. ➢ The 4th infralabial scale is the largest scale of other infralabial scales. ➢ The subcaudal (ventral scales distal to vent) are undivided and entire. ➢ Fangs are short, grooved and situated anteriorly ➢ Venom—neurotoxic.	Russell's Viper	➢ Zoological name: *Daboia russelii* ➢ Common names: Russell's viper, Chain viper ➢ Head is large, flat and triangular with small scales. White V-shaped mark present on head ➢ Pupils are vertical ➢ Large nostrils ➢ Body is stout and fatty with brown or yellowish color ➢ Body scales are semi-elliptical ➢ Three rows of chained dark spots present on back ➢ Tail is narrow and short. Scales are divided into two rows ➢ Fangs are long, curved, hollow, channelized and hinged ➢ When disturbed, makes a loud and hissing sound ➢ Venom—vasculotoxic and hemotoxic	
Contd...

Contd...

Saw-scaled Viper	Zoological name: *Echis carinatus* ➢ Common names: Saw-scaled vipers, Indian saw-scaled vipers ➢ Wide head, wider than their neck ➢ Large eyes ➢ Rough scaled snake ➢ Snake venoms are mostly of four types—neurotoxins, cardiotoxins, hemotoxins and cytotoxins	Sea snakes	Sea snakes are usually bluish, grayish or greenish in color. They have prominent nostrils and are situated on the top of snout: ➢ Body is flat and belly scales are not broad ➢ Tail is flattened and paddle shaped ➢ Venom—myotoxic	
Q. Discuss the clinical features and complications of poisonous (cobra) snakebite.

Signs, symptoms and complications of snakebite are listed in **Table 17.8**.

TABLE 17.8: Local and systemic features/complications of snakebites.

Local features	***Systemic features***
A. Elapid bite	
Fang marks, burning pain, swelling and discoloration, serosanguineous discharge. Local symptoms are milder than in viperine bite	**Preparalytic stage:** Vomiting, headache, giddiness, weakness, and lethargy **Paralytic stage: Ptosis**, ophthalmoplegia, drowsiness, convulsion, bulbar paralysis, respiratory failure, death, paradoxical respiration: Intercostal muscle paralysis, stomach pain (Krait), submucosal hemorrhage in stomach. Neck muscle weakness **(broken neck sign)** **Krait bites:** Present in early morning with paralysis and can be **mistaken for STROKE** These symptoms can be remembered as 5 Ds and 2 Ps ➢ *5 Ds—dyspnea, dysphonia, dysarthria, diplopia, dysphagia* ➢ *2 Ps—ptosis, paralysis*
B. Viperid bite	
Rapid swelling at bite site **Discoloration** **Blister formation** **Bleeding from bite site** **Pain**	➢ **Generalized bleeding:** Epistaxis, hemoptysis, hematemesis, bleeding gums, hematuria, melena, hemorrhagic areas over skin and mucosa ➢ **Lateralizing neurological symptoms** such as asymmetrical pupils, intracranial bleed ➢ **Hypotension:** Resulting from hypovolemia/direct vasodilation ➢ **Low back pain,** indicative of early renal failure ➢ **Muscle pain:** Rhabdomyolysis ➢ Parotid swelling, conjunctival edema, subconjunctival hemorrhage ➢ **Idiopathic systemic capillary leak syndrome (ISCLS)** characterized by episodes of severe hypotension, hypoalbuminemia, hemoconcentration without albuminuria ➢ **Renal failure:** Russell's viper, hump-nosed pit viper ➢ **Long-term complication:** Hypopituitarism and cardiotoxicity ➢ Saw-scaled viper generally does not cause renal failure
C. Hydrophid bite	
Local swelling **Pain**	Stiffness, myoglobinuria, renal failure

Asymptomatic (dry bite): Significant proportion of snakebites do not result in envenomation. Patients without clinical features of local or systemic envenomation should be closely observed for 24–48 hours.

Prognosis Assessment in Snakebite

See **Box 17.6.**

Laboratory Investigations

Q. IM20.6 **Choose and interpret the appropriate diagnostic testing in patients with snakebites.**

- **Bedside 20-minute whole blood clotting test (20-WBCT)**
  - Place 2 mL of freshly sampled venous blood in a small glass test tube and leave undisturbed for 20 minutes at ambient temperature. Gently tilt the test tube to see if the blood is still liquid; the patient has hypofibrinogenemia as a result of venom-induced consumption coagulopathy.
- **Nonspecific:** Hemogram, serum creatinine, serum amylase, creatine phosphokinase (CPK).
- Prothrombin time (PT), fibrinogen degradation product (FDP) and fibrinogen level in viper bite as it interferes with clotting mechanism.
- **LFT, ABG, and electrolyte:** For systemic manifestation.
- **Urine examination:** For proteinuria, myoglobinuria.
- **ECG:** Nonspecific changes such as bradycardia and atrioventricular (AV) block.

Box 17.6: Prognosis assessment in snakebite.

- Time of bite
- Activity at the time of bite
- First aid action taken since the bite
- Clinical examination
- **Twenty minutes whole blood clotting test (20-WBCT)**

Q. IM 20.3 **Describe the initial approach to the stabilization of the patient who presents with snakebite.**

Management

The first aid **(Box 17.7)** being currently recommended is based around the mnemonic: **"Do it RIGHT"**.

A. Specific treatment

Antisnake venom (ASV)

Indications for ASV are presented in **Table 17.9.**

Q. IM 20.7 **Enumerate the indications and describe the pharmacology, dose, adverse reactions, hypersensitivity reactions of antisnake venom.**

The classification of severity of snakebite is presented in **Table 17.10.**

- **Dosage of ASV:** Ideally administer within 4 hours but effective, if given within 24 hours:
  - In **mild cases, 5 vial (50 mL); in moderate cases, 5–10 vials; and in severe cases, 10–20 vial**.
  - Additional infusion containing 5–10 vials are infused until progression of swelling ceased and systemic symptoms are disappeared.
- **Mode of administration:** ASV is given slowly as IV injection or infusion at the rate of 2 mL/minute. ASV dilute 5–10 mL/kg body weight of normal saline or 5% dextrose and infused over 1 hour. ASV should never give locally at site of snakebite.
- No change in dose for children or pregnant women.
- **Repeat dose of ASV**
  - in vasculotoxic or hemotoxic envenomation: Administer ASV every 6 hours until coagulation (WBCT) is restored.
  - in neuroparalytic or neurotoxic envenomation: Initial dose of ASV 10 vials stat as infusion to be followed by 2nd dose of 10 vials if no improvement within 1st hour (total 20 vials).

Adverse reaction of ASV (Box 17.8): It may develop in 20% patients.

Box 17.7: First aid currently recommended for snakebite **"Do it RIGHT".**

R = Reassure the patient. Seventy percent of all snakebites are from nonvenomous species. Only 50% of bites by venomous species actually envenomate the patient

I = Immobilize in the same way as a fractured limb. Use of bandages or cloth is to hold the splints and should NOT block the blood supply or apply pressure. Do not compress by tight ligatures, because they can be dangerous! (Loose ligatures to block lymphatic flow can be used)

GH = Get to Hospital immediately. Traditional remedies have NO PROVEN benefit in treating snakebite

T = Tell the physician about any systemic symptoms that develop on the way to hospital (e.g., ptosis)

TABLE 17.9: Indications for antisnake venom (ASV).

- **Neurotoxicity**
- **Bleeding/coagulopathy**
  - Spontaneous systemic bleeding
  - WBCT (20-minute whole blood clotting test) > 20 minutes
  - Thrombocytopenia (platelet < 100,000)
- **Myoglobinuria/hemoglobinuria**
- Cardiac toxicity
- Local swelling involving more than half of the bitten limb
- Rapid extension of swelling
- Development of an enlarged tender lymph node draining the bitten limb
- Acute renal failure

TABLE 17.10: Classification of severity of snakebite.

	Envenomation			
	Absent	**Mild**	**Moderate**	**Severe**
Fang marks	±	+	+	+
Local reaction	–			
➢ Pain	Absent	Moderate	Severe	Severe
➢ Local edema	Absent	Minimum (0–15 cm)	Moderate (15–30 cm)	Severe >30 cm
➢ Erythema	Absent	+	+	+
➢ Ecchymosis	Absent	±	+	+
Systemic features	No	No	Weakness, sweating, syncope, nausea, vomiting, thrombocytopenia	Hypotension, paresthesia, ptosis, broken neck sign, coma, pulmonary edema, respiratory failure

Box 17.8: Adverse reactions of antisnake venom (ASV).

1. *Early anaphylactic reaction* ***(Table 17.11)****:* It may develop within 10 minutes to 3 hours. Patient should be monitored closely. *Treatment of anaphylactic reaction:*
   - Discontinue ASV
   - *Adrenaline:* 1:1,000 IM (0.5 mg/kg in adult and 0.01 mg/kg in children). It can be repeated every 5 minutes, if necessary.
   - *H1 antihistaminic:* IV 1 mg of chlorpheniramine maleate (CPM)
   - IV hydrocortisone
   - Once the patient has recovered, restart ASV slowly for 10–15 minutes keeping the patient under close observation. Then resume normal drip rate
2. *Late serum sickness:* Develops in 1–12 days. Characterized by fever, nausea, vomiting, diarrhea, arthritis, nephritis, myoglobinuria, etc. Treatment consists of:
   - *Oral antihistaminic:* 5-day course of oral antihistaminic. For adults—CPM 2 mg/6 hour and for children—0.25 mg/kg/day in divided dose
   - *Prednisolone:* For patient who fail to respond within 24 hours. Dose: 5 mg/6 hours in adult and 0.7 mg/kg/day in divided dose in children

TABLE 17.11: Any one of the following suggests early anaphylactic reaction.

Urticaria	Chills	Diarrhea	Hypotension
Itching	Nausea	Abdominal cramps	Bronchospasm
Fever	Vomiting	Tachycardia	Angioedema

Algorithm approach to the identification of type of snakebite is presented in **Flowchart 17.1**.

B. Supportive therapy

- **For coagulopathy:** If it does not reverse after ASV therapy, fresh-frozen plasma, cryoprecipitate (fibrinogen, factor VIII), fresh whole blood, platelet concentrate can be administered.
- **Management neurotoxic (neuroparalytic) envenomation**
  - ASV alone not sufficient.
  - Tracheostomy, endotracheal intubation, and mechanical ventilation.
  - ***Atropine neostigmine (AN)*** *dosage schedule: Atropine 0.6 mg followed by neostigmine (1.5 mg) to be given IV stat and repeat dose of neostigmine 0.5 mg with atropine every 30 minutes for 5 doses.* Thereafter to be given as tapering dose at 1, 2, 6 and 12 hours.
  - *Glycopyrrolate:* About 0.25 mg can be given before neostigmine in place of atropine as glycopyrrolate does not cross blood brain barrier.
- **Renal failure:** Hemodialysis/peritoneal dialysis.
- **Capillary leak syndrome:** Methylprednisolone (10 mg/kg Q8H) × 3 days.
- **Compartment syndrome:** Fasciotomy.
- **Surgical debridement of wound**
- **Care of bitten part:** Antibiotic prophylaxis and tetanus toxoid.

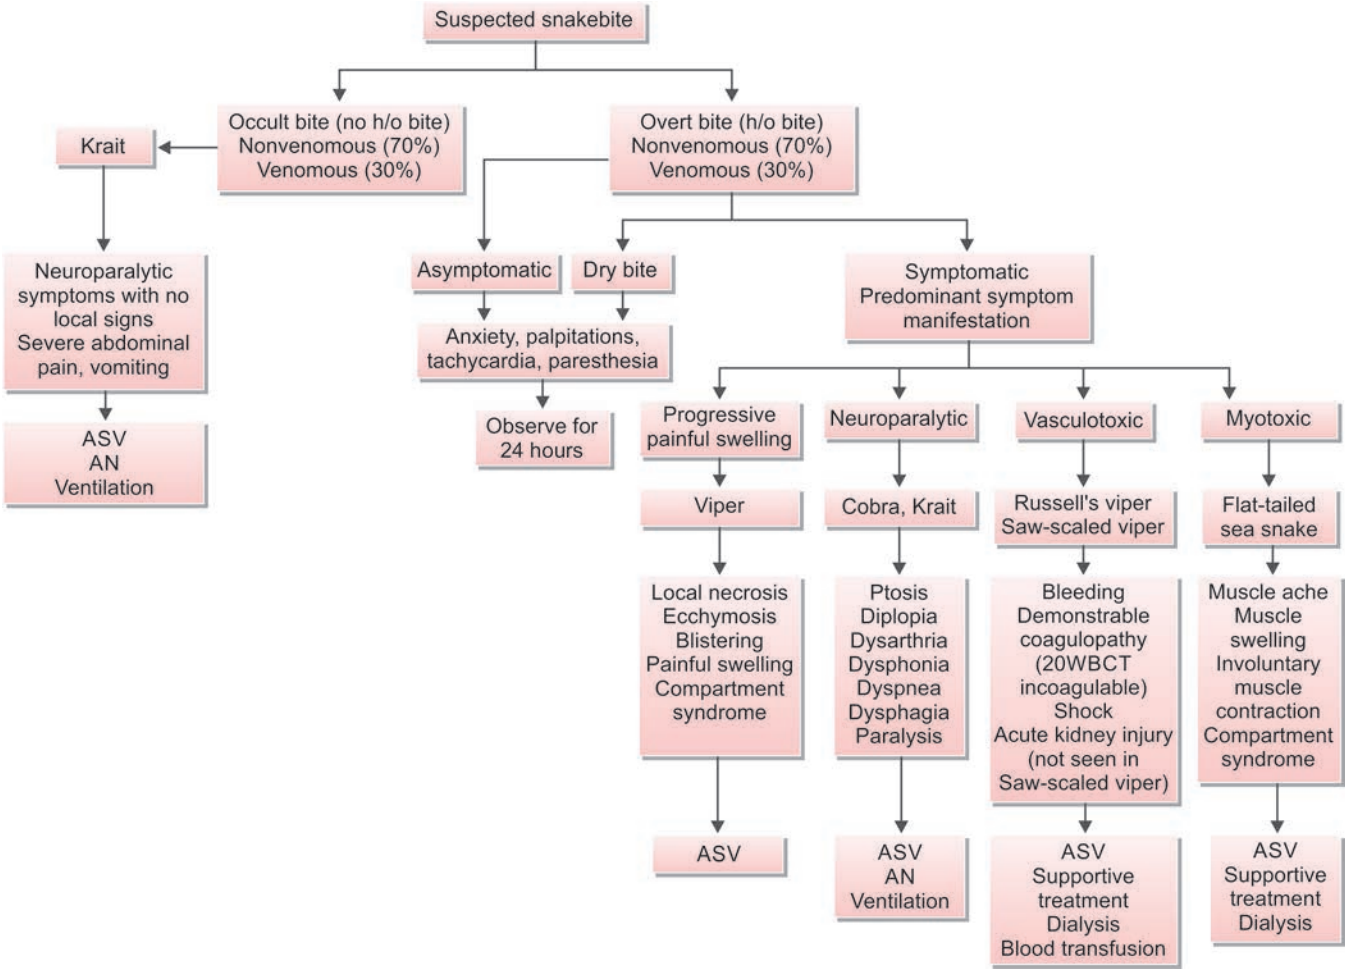
SCORPION BITE

Q. IM 20.8 **Describe the diagnosis, initial approach stabilization, and therapy of scorpion envenomation.**

Scorpion venom:

- It is clear, colorless toxalbumin and can be classified as either neurotoxic or hemolytic.
- Toxicity is more than snake. However, during bite only small quantity is injected.

FLOWCHART 17.1: Algorithm approach for the identification of type of snake bitten by clinical syndrome in snakebite and management of the same.



Suspected snakebite
Krait
Occult bite (no h/o bite) Nonvenomous (70%) Venomous (30%)
Overt bite (h/o bite) Nonvenomous (70%) Venomous (30%)
Neuroparalytic symptoms with no local signs Severe abdominal pain, vomiting
ASV AN Ventilation
Asymptomatic
Dry bite
Anxiety, palpitations, tachycardia, paresthesia
Observe for 24 hours
Symptomatic Predominant symptom manifestation
Progressive painful swelling

(ASV: Antisnake venom; AN: Atropine-neostigmine)

- Venom is strong autonomic stimulator and releases large amount of catecholamine from adrenals.
- Mortality (except in children) is negligible, and can cause acute pancreatitis.

Signs and Symptoms

1. **In case of hemolytic venom:**
    - Reaction is predominantly local and **simulates the viper snakebite.** However, the scorpion sting bite shows only one hole in the center of reddened area at the site of bite.
    - The extremity will have severe pain and edema.
2. **In case of neurotoxic venom:**
    - Symptoms are **similar to cobra bite.**
    - Usually no mark reaction in local area.
    - **Symptoms:** Nausea, vomiting, severe restlessness, paralysis, fever, cardiac arrythmia, convulsions, cyanosis, coma, and respiratory depression. Death may occur within hours from pulmonary edema and cardiac failure.

Diagnosis is confirmed by the enzyme-linked immunosorbent assay (ELISA) testing.

Treatment

- Immobilize the limb and apply a tourniquet above the sting
- Pack sting in ice, and incise and use suction, and wash with weak solution of ammonia, borax or potassium permanganate

- A local anesthetic (2% novocaine or 5% cocaine) is injected at site of pain
- A specific antivenom is available for most species
- Calcium gluconate IV to control local swelling
- Adrenergic symptoms (hypertension and/or pulmonary edema): **Prazosin** (selective peripheral alpha-1 adrenergic antagonist)
- Barbiturate to reduce convulsions
- Morphine is contraindicated. Give IV fentanyl 1 mg/kg for pain
- Atropine is valuable to prevent pulmonary edema
- Treatment of massive pulmonary edema: By oxygen, IV aminophylline or nitroprusside, NIV/CPAP

HYMENOPTERA (BEE, WASP, HORNET) STINGS

Q. IM 20.9 **Describe the diagnosis initial approach stabilization and therapy of bee sting allergy.**

- Hymenopteran stings only cause local inflammation in most people. Symptoms include pain, swelling, pruritis, bleeding.
- Large, local reactions (LLRs) develop in about 10% of hymenoptera stings and are due be immune IgE-mediated.
- In sensitized individuals, a single sting may result in rapid and potentially fatal anaphylaxis with hypotension (shock), bronchospasm, angioedema. Intramuscular 0.1% adrenaline can be lifesaving.
- Mass attacks by bees can be life-threatening even in nonsensitized individuals, through the direct action of venom causing hemolysis, rhabdomyolysis, pulmonary edema, acute renal failure, and adrenergic effects.
- No antivenom is available.
- Treatment is symptomatic.

CORROSIVE POISONING

Q. IM 21.3 **Enumerate the common corrosives used in your area and describe their toxicology, clinical features, prognosis, and approach to therapy.**

Common corrosive poisons:

- Acids (hydrochloric, acetic, sulfuric, lactic, oxalic, carbolic)
- Alkalis (sodium and potassium, soaps, detergents)
- Heavy metal salts (sublimate)
- Others: Formalin, iodine tincture

Clinical Features

- Clinical presentation of corrosive injuries in the upper gastrointestinal tract. Acids cause coagulative necrosis while alkalis cause liquefactive necrosis.
- Patient complains of oropharyngeal, epigastric, or retrosternal pain associated with dysphagia or odynophagia, and/or hypersalivation, nausea, vomiting, hematemesis. Severe forms can damage larynx, and also cause endotracheal or bronchial necrosis with mediastinitis, also perforation of stomach may occur.
- Late complications are esophageal strictures and stenosis, gastric stenosis of the antrum and pylorus, esophageal and stomach cancer.

Treatment

- Treatment mainly is to prevent the complications.
- Lavage is contraindicated.
- Upper gastrointestinal (GI) endoscopy should be performed during the first 24 hours after ingestion in order to evaluate the extent of esophageal and gastric damage, establish prognosis, and guide therapy
- Grading of corrosive injury based on endoscopy:
  - 0: Normal mucosa
  - 1: Erythema/hyperemia
  - 2a: Superficial ulcer/erosion/friability/hemorrhage/exudates
  - 2b: Findings in 2a + deep discrete/circumferential ulcers
  - 3a: Scattered/focal necrosis (black/gray discoloration)
  - 3b: Extensive/circumferential necrosis of mucosa
- Antibiotics are recommended in grade 3 injury and suspected gastrointestinal perforation.
- Proton pump inhibitors and H2 blockers are routinely recommended.

- Nutrition is planned according to the endoscopic grade of the lesions. Patients with grade 1/2a can tolerate oral feeds and those with grade 2b/3a will require nasoenteral feeding. Patients with grade 3b lesions require gastrostomy/jejunostomy for enteral feeding and may also require total parenteral nutrition.
- 30% of patients usually develop esophageal strictures with 2 months which will need endoscopic dilatation or surgery.

COMMON DRUG OVERDOSAGES

Q. IM 21.4 Enumerate the commonly observed drug overdose in your area and describe their toxicology, clinical features, prognosis and approach to therapy.

Sedative Drug Poisoning

Benzodiazepines Poisoning

Q. Write a short essay/note on benzodiazepine overdose and management.

Mode of Action

- Benzodiazepines (BZDs) exert their effect via modulation of the gamma-aminobutyric acid-A (GABA-A) receptor.
- Gamma-aminobutyric acid is the main inhibitory neurotransmitter of the central nervous system.

Types (Table 17.12)

TABLE 17.12: Various categories of benzodiazepines.

Hypnotic	*Antianxiety*	*Anticonvulsant*
➢ Diazepam ➢ Flurazepam ➢ Nitrazepam ➢ Alprazolam ➢ Temazepam ➢ Triazolam	➢ Diazepam ➢ Chlordiazepoxide ➢ Oxazepam ➢ Lorazepam ➢ Alprazolam	➢ Diazepam ➢ Lorazepam ➢ Clonazepam ➢ Clobazam

Clinical features of overdosage

Oral benzodiazepines taken in overdose without a coingestant rarely cause significant toxicity. The classic presentation of a patient with an isolated BZD overdose consists of CNS depression with normal vital signs.

- **Toxic symptoms:** Sedative action on the CNS.
- **Large doses:** Neuromuscular blockade.
- **Intravenous injection:** Peripheral vasodilation, fall in BP, shock. Propylene glycol (1,2-propanediol) is the diluent used in parenteral formulations of diazepam and lorazepam which itself causes cardio- and neurotoxicity.

Of note, most intentional ingestions of BZDs involve a coingestant, the most common being *ethanol*.

Acute poisoning

- **Mild:** Drowsiness, ataxia, weakness.
- **Moderate to severe:** Vertigo, slurred speech, nystagmus, partial ptosis, lethargy, hypotension, respiratory depression, coma (stages 1 and 2).
  - **Coma (stage 1):** Responsive to painful stimuli but not to verbal or tactile stimuli, without any disturbance in respiration or BP.
  - **Coma (stage 2):** Unconscious, not responsive to painful stimuli, no disturbance in respiration or BP.

General Diagnostic Testing

- Check glucose, to rule out **hypoglycemia** as the cause of any alteration in mental status.
- **Acetaminophen and salicylate levels**, to rule out these common co-ingestions.
- Electrocardiogram, as it affect the QRS or QTc intervals.
- Pregnancy test in women of childbearing age.

Life Supportive Procedures and Symptomatic/Specific Treatment

- Airway, breathing and circulation
- Endotracheal intubation
- Assisted ventilation
- Supplemental oxygen intravenous fluids, inotropes, if needed.

Decontamination

Gastrointestinal decontamination with activated charcoal (AC) (usually of no benefit in cases of isolated BZD ingestion and increases the risk of aspiration).

Antidote Treatment: Flumazenil

- *Mode of action:* Competitive antagonism. Complete reversal of benzodiazepine effect with a total slow IV dose of 1 mg.
- Administered in a series of smaller doses beginning with 0.2 mg and progressively increasing by 0.1–0.2 mg every minute until a cumulative total dose of 3.5 mg is reached.
- Resedation occurs within 0.5–2 hours.
- *Side effects:* Nausea, vomiting, arrhythmias, convulsions.
- *Contraindication:* Status epilepticus.

Barbiturate Poisoning

Q. Write a short essay on clinical features and treatment of barbiturate poisoning.

- Nonselective CNS depressants.
- **Mode of action:** Direct CNS depressants bind to GABA receptors → prolongs the opening of chloride channel. Inhibits excitable cells of the CNS.

Classification

See **Table 17.13**.

TABLE 17.13: Classification of barbiturates.

Long acting (6–12 hours)	*Intermediate acting (3–6 hours)*	*Short acting (<3 hours)*	*Ultrashort acting (<15–20 minutes)*
➢ Mephobarbital ➢ Phenobarbitone	➢ Amobarbital Aprobarbitone Butobarbitone	➢ Hexobarbitone ➢ Pentobarbitone Secobarbital	➢ Thiopentone Methohexitone

Signs and Symptoms

See **Table 17.14.**

TABLE 17.14: Adverse and toxic effects of barbiturate poisoning.

Adverse effects	*Toxic effects*
➢ Residual depression ➢ Paradoxical excitement ➢ Hypersensitivity reactions—localized swelling of eyelid, cheek or lip, erythematous or exfoliative dermatitis ➢ Synergistic action with ethanol and antihistamines	➢ Slurred speech, ataxia, lethargy, confusion, headache, and nystagmus CNS depression, coma, shock ➢ Pupils—first constricted, later dilate because of hypoxia ➢ Hypothermia ➢ Cutaneous **bullae** (blisters) **(Fig. 17.7)** ➢ Death due to respiratory arrest or cardiovascular collapse

Management of Barbiturate Poisoning

- No specific antidote.
- Barbiturate poisoning is more **dangerous** than benzodiazepine poisoning.
- Management is **supportive**.
  - Cardiorespiratory support.
  - Clean the airways by thorough suctioning and insertion of oral airways.
  - If the patient is comatose, prompt intubation is strongly advocated because of worsening of respiratory failure.
  - Correction of dehydration by CVP-guided fluid therapy depending on the serum electrolytes.
  - Treat hypotension by intravenous infusion of plasma expanders and vasopressors. In refractory cases, steroids are given.
  - Measures to prevent absorption:
    - Gastric lavage
    - Activated charcoal is administrated orally or by nasogastric tube.
  - Measures for removal of barbiturates:
    - Frequent doses of activated charcoal
    - Forced diuresis with alkalization of urine
    - Hemodialysis and hemoperfusion.

Analgesic Poisoning

Paracetamol (Acetaminophen) Poisoning

Q. Write a short essay on paracetamol poisoning and its treatment.

- Toxicity unlikely to result from a single dose of <150 mg/kg in child or 7.5–10 g for adult.
- Toxicity is likely with single ingestions > 250 mg/kg or those > 12 g over a 24-hour period.
- Virtually all patients who ingest doses in excess of 350 mg/kg develop severe liver toxicity unless appropriately treated.

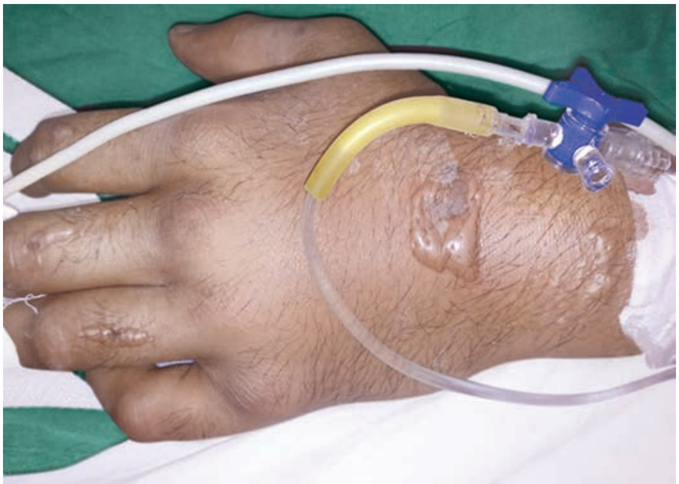

FIG. 17.7: Barbiturate blister.

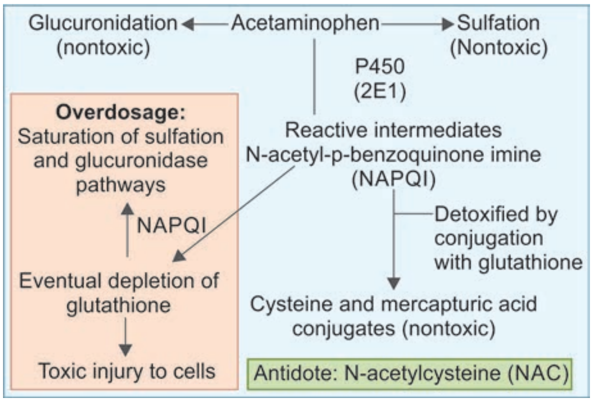


Glucuronidation (nontoxic)
Acetaminophen
Sulfation (Nontoxic)
P450 (2E1)
Overdosage: Saturation of sulfation and glucuronidase pathways
NAPQI
Eventual depletion of glutathione
Toxic injury to cells
Reactive intermediates N-acetyl-p-benzoquinone imine (NAPQI)
Detoxified by conjugation with glutathione
Cysteine and mercapturic acid conjugates (nontoxic)
Antidote: N-acetylcysteine (NAC)

FIG. 17.8: Acetaminophen metabolism.

Mechanism of Paracetamol Toxicity (Fig. 17.8)

Toxicity is due to formation of an intermediate reactive metabolite, which binds covalently to cellular proteins, leading to cell death. This causes hepatic and occasionally renal failure. In therapeutic doses, the toxic intermediate metabolite is detoxified in reactions requiring glutathione. **With overdose, glutathione reserves become depleted**.

Clinical Manifestations of Toxicity

- **Stage I (0.5–24 hours)**
  - No symptoms; nausea, vomiting and malaise.
- **Stage II (24–72 hours)**
  - Subclinical elevations of hepatic aminotransferases (AST, ALT).
  - Right upper quadrant pain, with liver enlargement and tenderness. Elevations of prothrombin time (PT), total bilirubin, and oliguria and renal function abnormalities may become evident. Acute kidney injury is primarily **due** to acute tubular necrosis.
- **Stage III (72–96 hours)**
  - Fulminant hepatic failure; jaundice, confusion (hepatic encephalopathy), a marked elevation in hepatic enzymes, hyperammonemia, and a bleeding diathesis, hypoglycemia, lactic acidosis, renal failure (25%), and death.
- **Stage IV (4 days to 2 weeks)**
  - Recovery phase that usually begins by day 4 and is complete by 7 days after overdose.

Treatment Options

- **Activated charcoal:** May reduce absorption by 50–90%.
- **Gastric lavage:** Only for massive ingestions (e.g., > 600 mg/kg).
- **Antidote: N-acetylcysteine (NAC) (Box 17.9)**
  - *Properties:*
    - *Mechanism of action (MOA):* A glutathione precursor.
    - Limits the formation and accumulation of NAPQI.
    - Powerful anti-inflammatory and antioxidant effects.
  - *Dosage and administration:*
    - IV infusion.
  - 150 mg/kg over 15 minutes; 50 mg/kg over next 4 hours; 100 mg/kg over next 16 hours up to 36 hours.
  - Most effective, if started within 8–10 hours after ingestion.
  - Beyond 8 hours, NAC efficacy progressively decreases.
    - Oral N-acetylcysteine regimen consists of a 72-hour oral course given as a 140 mg/kg loading dose followed by 17 doses of 70 mg/kg every 4 hours (total dose 1,330 mg/kg).
- Alternate medication: **Oral methionine.**
- **Liver transplantation (Box 17.10)**
  - It is life-saving for fulminant hepatic necrosis.

Box 17.9: Indications for N-acetylcysteine in paracetamol poisoning.

- All patients with a serum acetaminophen concentration above the possible hepatic toxicity line on the Rumack-Matthew nomogram
- Patients with an estimated ingestion of > 140 mg/kg
- Patients with an unknown time of ingestion
- Patients with a presentation > 24 hours after ingestion with elevated transaminases

Box 17.10: Indications for liver transplantation for paracetamol poisoning (King's College Criteria).

- Acidosis (pH <7.3)
- PT (prothrombin time) >100 sec
- Creatinine >3.4 mg/dL
- Grade 3 encephalopathy (or worse)

Aspirin Toxicity

Q. **Write a short note on salicylates poisoning and its management.**

Mechanism of toxicity

- Acetylsalicylic acid (ASA) is hydrolyzed to salicylic acid. Responsible for therapeutic and toxic effects.
- *Direct stimulation of respiratory center:* Medulla.
- *Uncouples oxidative phosphorylation:*
    - Increase in O_2 consumption and CO_2 production.
    - Increase respiration leading to respiratory alkalosis.
- *Renal excretion of bicarbonate, Na and K:* Metabolic acidosis.
- *Inhibition of mitochondrial respiration:* Increase pyruvate and lactic acid → metabolic acidosis.
- Disruption of Kreb's cycle metabolism and glycolysis → hyperglycemia, ketonemia.

Signs and symptoms (Table 17.15 and Box 17.11)

Salicylate poisoning can occur in two settings—an **acute toxicity and a chronic toxicity (Table 17.16)**.

Management of Aspirin Overdose

- **Initial supportive therapy**

Specific Management

- *Decreasing absorption*
    - **Activated charcoal:** Given in those who have taken >250 mg/kg body weight <1 hour ago.
    - **Gastric lavage:** It is advised in patients who have taken >500 mg/kg body <1 hour ago.
- *Increasing drug elimination*
    - **Urinary alkalinization:**
        - Alkalinizing urine from pH 5–8 increases renal elimination of ASA from 1.3 to 100 mL/minute.
        - Serum half-life decreases from 48 to 6 hours.
        - This is done by giving an infusion of sodium bicarbonate.
    - **Hemodialysis (Box 17.12):**
        - Used in severe life-threatening overdose.
        - Aims to correct the acid-base disturbances while removing the salicylate.

TABLE 17.15: Differences between acute and chronic aspirin toxicity.

Features	*Acute*	*Chronic salicylism*
Age	Young adult	Older adults/infants
Cause	Overdose	Treatment misuse
Coingestion	Frequent	Rare
Mental status	Normal	Altered
Clinical presentation	Early	Late
Mortality	Low with treatment	High
Serum levels (mg/dL)	40 to ≥120	30 to ≥80

Box 17.11: ASPIRIN mnemonic.

- **A**ltered mental status (lethargy—coma)
- **S**weating/diaphoresis
- **P**ulmonary edema
- **I**ncreased vital signs (hypertension, increased respiratory rate, tachycardia)
- **R**inging in the ears
- **I**rritable
- **N**ausea and vomiting

Cyanide Poisoning

Q. FM 9.6 **Write a short essay on management of cyanide poisoning.**

Cyanide

- Present in bitter almonds (250 mg CN/100 g plant tissue), cassava (104 mg CN/100 g plant tissue), wild cherries (140–370 mg CN/100 g plant material), and other foods.
- Used extensively in industry for fumigation, electroplating, and mining activities.

Routes of exposure of cyanide is mentioned in **Box 17.13**.

TABLE 17.16: Features of salicylate poisoning.

Central nervous system	*Signs and symptoms*	*Laboratory findings*
➢ Hyperactivity ➢ Irritability ➢ Delirium ➢ Agitation ➢ Vertigo ➢ Slurred speech ➢ Hallucination ➢ Lethargy ➢ Stupor ➢ Seizures ➢ Coma ➢ Cerebral edema	➢ Nausea, vomiting ➢ Tinnitus, hearing loss ➢ Pulmonary edema ➢ Hyperventilation (tachypnea and/or hyperpnea) ➢ Hyperthermia ➢ Tachycardia ➢ Volume depletion ➢ Arrhythmias ➢ Diaphoresis	➢ Respiratory alkalosis ➢ Anion gap metabolic acidosis ➢ Coagulation abnormalities ➢ Urinary ketones ➢ Hyperkalemia ➢ Hyperlactatemia (mild)

Box 17.12: Absolute indications for hemodialysis in aspirin toxicity.

- Renal failure
- Congestive heart failure
- Acute lung injury
- Persistent CNS disturbances
- Progressive deterioration in vital signs
- Severe acid-base or electrolyte imbalance, despite appropriate treatment
- Hepatic compromise with coagulopathy
- Salicylate concentration (acute) >100 mg/dL (in the absence of the above)

Box 17.13: Routes of exposure of cyanide.

- **Gas:** Inhalation (e.g., hydrogen cyanide and cyanogen chloride)
- **Liquid:** Inhalation (aerosol), ingestion, skin contact (e.g., hydrocyanic acid)
- **Solid:** Inhalation, ingestion, skin contact (e.g., cyanide salts)

Clinical Manifestations of Cyanide Poisoning

- **Onset of cyanide poisoning**
    - **Inhalation** (rapid onset, seconds to minutes), **ingestion,** and **skin contact** (delayed onset, 15–30 minutes).
- Death may occur within 6–8 minutes after inhalation of a high concentration 2–5 mg/kg of it is lethal.
- **Mechanism:** Inhibits mitochondrial cytochrome oxidase and an "asphyxiating" agent.
- Common final pathway for cyanide intoxication is **cellular hypoxia**.
    - **Metabolic acidosis:** Nonspecific symptoms.
    - **CNS: Dizziness, nausea, vomiting, drowsiness**, **tetanus, trismus, hallucinations**.
    - **CVS: Dysrhythmia, hypotension**. Tachycardia and hypertension may occur transiently in early stages.
    - **Respiratory: Dyspnea, initial hyperventilation followed by hypoventilation** and **pulmonary edema**. Cyanosis not apparent, since blood is adequately oxygenated.

Laboratory Diagnosis

- **Blood cyanide levels** can be estimated, but empiric treatment is almost always required before laboratory results are available.
- **High anion gap metabolic acidosis.**
- **Arterial and venous pO_2 may be elevated.**

Treatment

- **Activated charcoal:** For alert, asymptomatic patients following ingestion.
- **Supplemental oxygen:** 100% for suspected exposure.
- Supportive care.
- **Sodium nitrite:**
    - **Mechanism: Forms methemoglobin**, competes with cytochrome oxidase for free cyanide; combines with cyanide to form cyanmethemoglobin.
    - **Dose:** (1) Adults: 300 mg IV over 5 minutes; slower if hypotension develops and (2) children: 0.12–0.33 mg/kg IV infused as above.
- **Amyl nitrite: 0.3 mL inhaled can be repeated after 3–5 minutes**. Second-line agent used when sodium nitrite is not available.
- **Sodium thiosulfate:**
    - **Mechanism:** Sulfur donor promotes rhodanese activity, detoxifies cyanide as it is released from cyanmethemoglobin. Directly detoxifies cyanide by conversion to thiocyanate; too slow to be useful as a first-line intervention.
    - **Dose:** (1) *Adults:* 12.5 g IV over 10–20 minutes following administration of sodium nitrite and (2) *Children:* 412.5 mg/kg IV over 10–20 minutes.

Hydroxocobalamin

- **Mechanism:** Direct-binding agent, **chelates cyanide.**
- **Dose:** 4–5 g IV

Dicobalt edetate is an intravenous chelator of cyanide which can be used.

Anticholinergic Toxidrome

Q. Write a short essay/note on causes of anticholinergic syndrome.

Causes of Anticholinergic Toxidrome

See **Table 17.17.**

TABLE 17.17: Various causes of anticholinergic syndrome.

Natural alkaloids	**Synthetic compounds**
➢ Atropine (from the plant *Atropa belladonna*/Deadly nightshade) ➢ Hyoscine (Scopolamine) (from *Hyoscyamus niger*/henbane) ➢ *Datura stramonium* (plant—Jimson weed/Angel's trumpet)	➢ *Mydriatics:* Tropicamide (eye drops) ➢ *Antisecretory antispasmodics:* Glycopyrrolate, oxybutynin ➢ *Antiparkinsonian drugs:* Benzhexol, benztropine
Semisynthetic derivatives	**Miscellaneous**
➢ Homatropine (eye drops) ➢ Tiotropium bromide	➢ Tricyclic antidepressants, e.g., amitriptyline ➢ Phenothiazines, e.g., prochlorperazine ➢ Antihistamines, e.g., cyclizine ➢ Neuroleptics, e.g., olanzapine

PLANT POISONS

Q. Enumerate the common plant poisons seen in your area and describe their toxicology, clinical features, prognosis and specific approach to detoxification.

Neurotoxic Plant Poisons

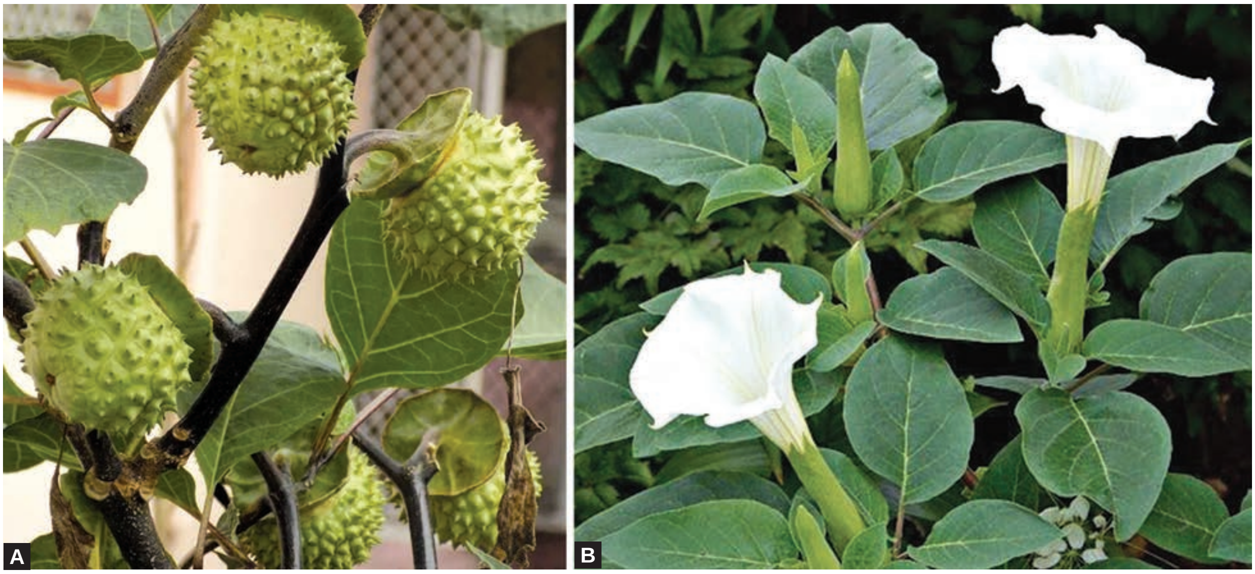
Datura Poisoning

Write a short essay/note on clinical features and management of datura poisoning.

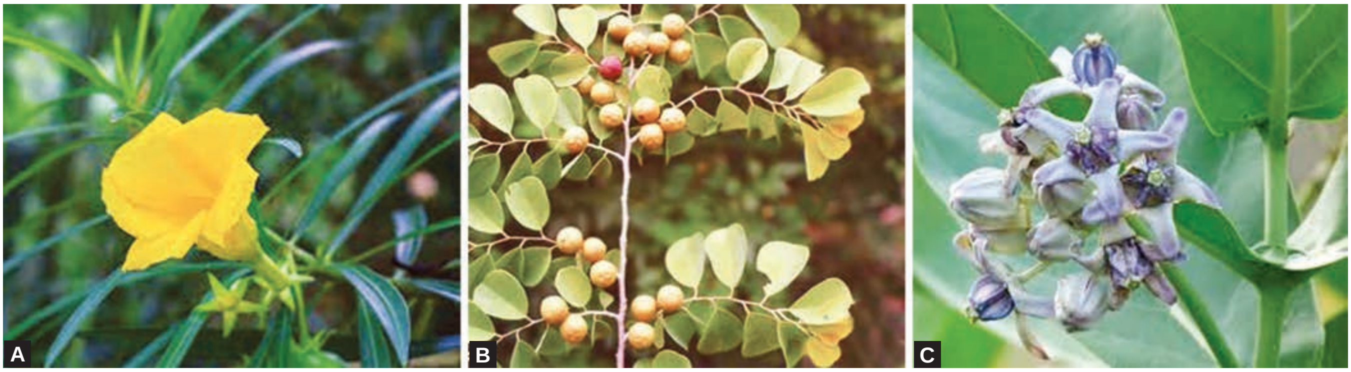
- *Datura stramonium* (jimson seed) **causes anticholinergic syndrome.** The active **toxic agents include atropine and scopolamine.** Atropine and related compounds **block acetylcholine at the receptor sites of postganglionic synapses of the cholinergic nerves.**
- **All the parts of *datura* plant (Figs. 17.9A and B) are poisonous,** but the seeds and fruit are the most toxic.
- **Mode of poisoning:** Most popular mode of poisoning is by mixing the seeds in sweets and given to others with the intention of thefts.

Clinical features

- Toxic symptoms often appear within 30 minutes of ingestion and last for 24–48 hours.
- Clinical features include tachycardia and the other features are described as ***"blind as a bat, mad as a hatter, red as a beet, hot as a hare, dry as a bone, the bowel and bladder lose their tone, and the heart runs alone".***
  - *Hot as a hare:* Cutaneous vasodilatation leading to anhidrotic hyperthermia.
  - *Blind as a bat:* Ciliary muscle paralysis, mydriasis, dilated pupils.
  - *Dry as a bone:* Anhidrosis, dryness of mouth, urinary retention, decreased bowel motility.
  - *Red as a beet:* Cutaneous vasodilatation causing flushing.
  - *Mad as a hatter:* CNS arousal, agitation, delirium, hallucinations.



FIGS. 17.9A AND B: *Datura*: (A) Seed; (B) Flower.



FIGS. 17.10A TO C: (A) Oleander plant; (B) *Cleistanthus collinus*; (C) *Calotropis*.

- It can be fatal-producing stupor, coma, and convulsions. Death is due to respiratory paralysis or cardiovascular collapse.

Management

- Gastric lavage and supportive therapy.
- Control of hyperthermia.
- Role of physostigmine, a cholinesterase inhibitor is not clear.
- Activated charcoal adsorbs the alkaloids.
- Benzodiazepines to treat agitation.

Cardiotoxic Plant Poisons (Figs. 17.10A to C)

Cardiotoxic plant poisons inhibit Na^+/K^+-ATPase pump leading to overall increase in intracellular Na^+ ions and secondary increase in intracellular Ca^{2+} levels.

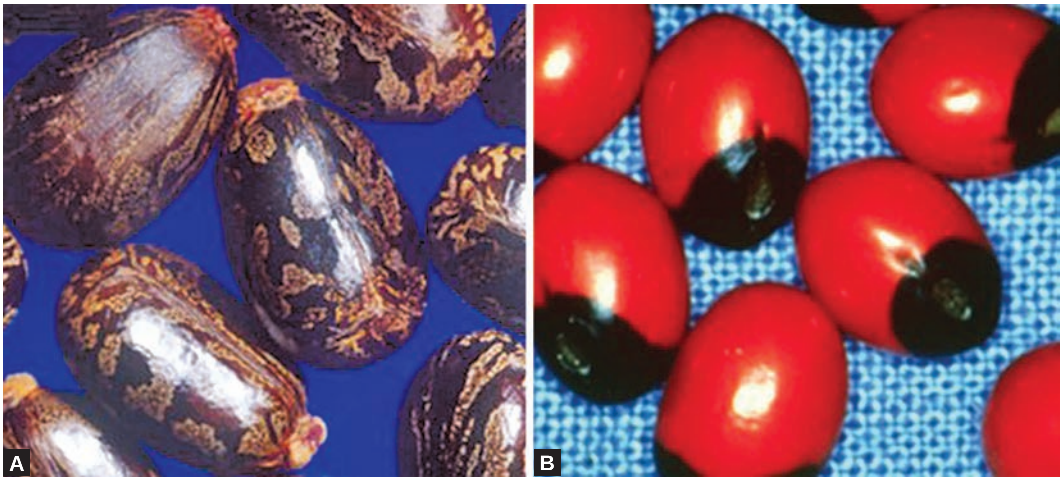
- *Symptoms:* On ingestion, they produce burning sensation, abdominal pain, nausea, vomiting, diarrhea, dizziness and numbness in oral and perioral region.
- Most important cardiotoxic effects are sinus bradycardia, varying degrees of heart block, ventricular ectopics, ventricular tachycardia which can be fatal.

Management of Cardiotoxicity

- Atropine 0.6 mg, orciprenaline 10 mg to maintain heart rate around 80/minute. Severe bradycardia may need pacemaker insertion.
- Sodium bicarbonate 50 mL IV 6th hourly, if ABG shows acidosis.

Gastrointestinal Toxic Plant Poisons

Ricinus communis **(Fig. 17.11A)** contains ricin and *Abrus precatorius* **(Fig. 17.11B)** contains abrin.



FIGS. 17.11A AND B: (A) *Ricinus communis* contains ricin; (B) *Abrus precatorius* contains abrin.

Clinical Features

- Gastrointestinal upset, vomiting, diarrhea, abdominal pain, GI bleeding.
- Hematuria, acrocyanosis, shock, dehydration, and hemolysis.
- Abnormal liver function tests (LFTs) and renal function tests (RFTs).

Treatment: Supportive.

Opioid Poisoning

Q. Write a short essay/note on opiate overdosage, clinical features of opioid tolerance, and its management.

Opium is extracted from poppy seeds (*Papaver somniferum*) **(Fig. 17.12)**.

FIG. 17.12: Poppy seeds.

Opioid agonists: Morphine, heroin, hydromorphone, fentanyl, codeine.

Opioid Tolerance

- Tolerance is a **diminished responsiveness to the drug's action** that is seen with many compounds.
- Tolerance can be demonstrated by a decreased effect from a constant dose of drug or by an increase in the minimum drug dose required to produce a given level of effect.
- **Physiological tolerance** involves changes in the binding of a drug to receptors or changes in receptor transductional processes related to the drug of action. This type of tolerance **occurs** in opioids.
- Molecular basis of tolerance involves glutaminergic mechanisms (glutamate—excitatory amino acid neurotransmitter).
- **Physiological dependence occurs when the drug is necessary for normal physiological functioning—this is demonstrated by the withdrawal reactions.**
- **Withdrawal reactions** are usually the **opposite of the physiological effects** produced by the drug.

Opioid toxicity is related to opioid receptors in non-nociceptive pathways and counteropioid responses. It is determined by genetics, organ function, and co-medications.

Acute action and withdrawal signs of opioids are listed in **Table 17.18**.

TABLE 17.18: Acute action and withdrawal signs of opioids.

Acute action	*Withdrawal signs*	*Acute action*	*Withdrawal signs*
➢ Analgesia	➢ Pain and irritability	➢ Constipation	➢ Diarrhea
➢ Respiratory depression	➢ Hyperventilation	➢ Pupillary constriction	➢ Pupillary dilation
➢ Euphoria	➢ Dysphoria and depression	➢ Hypothermia	➢ Hyperthermia
➢ Relaxation and sleep	➢ Restlessness and insomnia	➢ Drying of secretions	➢ Lacrimation, runny nose
➢ Tranquilization	➢ Fearfulness and hostility	➢ Reduced sex drive	➢ Spontaneous ejaculation
➢ Decreased blood pressure	➢ Increased blood pressure	➢ Flushed and warm skin	➢ Chilliness and "gooseflesh"

CARBON MONOXIDE

Q. FM9.2 Write a short note on carbon monoxide poisoning—signs and symptoms.

Carbon monoxide (CO) is a colorless, odorless gas generated by faulty appliances burning organic fuels. It is also present in vehicle exhaust fumes. It produces toxicity by binding with hemoglobin and cytochrome oxidase, which decreases the delivery of oxygen to tissue and inhibits cellular respiration.

Clinical Features

Acute severe CO poisoning produces non-specific symptoms such as headache, nausea, irritability, weakness, and tachypnea. Skin changes, i.e., cherry red/pink discoloration of skin is also seen. Later, ataxia, nystagmus, drowsiness, and hyperreflexia may develop leading to coma, respiratory depression, cardiovascular collapse, and death. Myocardial ischemia/infarction, cerebral edema, and rhabdomyolysis (with myoglobinuria and renal failure) may occur. Long-term exposure can lead to Parkinsonism.

Treatment of Carbon Monoxide Poisoning

Administration of normobaric 100% oxygen is the therapy of choice for most cases, while hyperbaric oxygen therapy is reserved for severe poisonings.

Treatment of opioid toxicity

- Ensure adequate ventilation
- Management of complications such as ARDS

Antidote—Naloxone, Naltrexone

- **MOA:** Pure opioid antagonist competes and displaces narcotics at opioid receptor sites.
- **Naloxone:** IV (preferred), IM, intratracheal, subcutaneous: 0.4–2 mg every 2–3 minutes as needed.

ALCOHOL POISONING

Methanol Poisoning

Q. PH1.21 Write a short note on toxicity, clinical features, and management of methanol poisoning.

- Methanol is a mild CNS depressant.
- *Metabolism:* Methanol itself is not toxic. However, its metabolites namely formaldehyde and formic acid are responsible for its toxicity.

Clinical Features

- Early clinical features are due to methanol, whereas late features are due to the methanol metabolite formic acid.
    - **Features due to methanol:** Methanol produces nausea, vomiting, abdominal pain, headache, vertigo, confusion, obtundation, convulsions, and coma.
    - **Features due to formic acid:** Metabolic acidosis and **retinal injury**. The retinal manifestations include clouding and diminished vision, dancing and flashing spots, dilated or fixed pupils, and hyperemia of the optic disc, retinal edema, and blindness.
- **Other manifestations:** Rapid breathing due to metabolic acidosis, myocardial depression, bradycardia, shock, and anuria.
- **Complication:** Putaminal necrosis producing rigidity, tremor, masked faces, and monotonous speech.

Diagnosis

- Confirmation by **measurement of serum methanol level,** which is usually > 20 mg/dL.
- Methanol-induced formic acidosis can be confirmed by a large anion gap, low serum bicarbonate, and elevated serum formate levels.
- Osmolal gap is elevated due to methanol.

Ethylene Glycol Poisoning

- Produces similar symptoms as methanol poisoning; however, renal failure is more common.
- Treatment is on same lines as methanol poisoning. Supplementation of thiamine and pyridoxine as cofactor therapy.

Management

- **In early stages:**
    - **Gastrointestinal decontamination**
    - **Correction of systemic acidosis** with sodium bicarbonate.
- **Ethanol therapy:** Indicated in patients with visual symptoms or methanol level exceeding 20–30 mg/dL. Ethanol blocks conversion of methanol to formic acid by inhibiting alcohol dehydrogenase.
- **Hemodialysis:** Indicated (1) when methanol level exceeding 50 mg/dL, (2) those with visual signs, and (3) those with metabolic acidosis unresponsive to bicarbonate.
- **Antidote of methanol poisoning:** 4-methylpyrazole or **fomepizole (15 mg/kg IV, followed by 10 mg/kg every 12 hours)** is a direct, potent inhibitor of alcohol dehydrogenase. It may be more effective than ethanol, which is a competitive antagonist.
- **Co-factor therapy: Leucovorin 50 mg IV or folic acid 50 mg IV every 6 hours** is given in addition to ethanol or 4-methylpyrazole. It acts by enhancing the rate of degradation of formic acid to carbon dioxide.

Ethanol Poisoning

Q. PH1.21 Describe the symptoms and management of ethanol poisoning.

- Alcohol belongs to inebriant group of neurotics class of poisons.
- **Stages of alcohol intoxication:**
    - Stage of excitement: Increased talkativeness, increased self-confidence, decreased sensory perception, loss of fine motor skills, slowed information processing, increased sexual desires

  - Stage of incoordination: Incordination of thought, speech, impaired judgment, confusion, slurred speech, staggering gait, dilated pupils.
  - Stage of narcosis: Deep sleep, rapid pulse, hypothermia, labored breathing, miosis → coma → death. Patients can manifest with other complications like hematemesis, pancreatitis, head injury.
- **Management:**
  - Rule out more serious conditions such as head trauma, hypoxia, hypoglycemia, hypothermia, hepatic encephalopathy, and other metabolic derangements.
  - ABG will reveal high anion gap acidosis.
  - Gastric lavage is not helpful because of the rapid rate of absorption of ethanol from the gastrointestinal tract.
  - Dextrose saline with 100 mg thiamine has to be administered.
  - Benzodiazepines, first-generation (typical) antipsychotics and ketamine can be used to control the agitation.
  - Hemodialysis is useful for severely elevated ethanol levels and severe acidosis.
  - Post-recovery patients need psychotherapy and rehabilitation.

Aluminum Phosphide Poisoning

Q. Discuss the clinical features and management of aluminum phosphide poisoning.

Aluminum phosphide (ALP) poisoning is known worldwide, especially in developing countries such as India. Lethal dose of ALP is 1–1.5 g.

Aluminum phosphide, when ingested, liberates a lot of phosphine gas → phosphine leads to noncompetitive inhibition of the cytochrome oxidase of mitochondria, blocking the electron transfer chain and oxidative phosphorylation, producing an energy crisis in the cells.

The severe toxicity of ALP particularly affects the cardiac and vascular tissues, which manifests as profound and refractory hypotension, congestive heart failure, methemoglobinemia, myocarditis, pericarditis and subendocardial infarction, cardiac arrhythmias, lactic acidosis, and respiratory failure.

Management

It is supportive, the main objective is to provide effective oxygenation, ventilation, and circulation till phosphine is excreted. Gastric decontamination using activated charcoal, potassium permanganate, and medicated liquid paraffin have been tried. No definite antidote available.

Rodenticide Poisoning

Q. Discuss the clinical features and management of rodenticide poisoning.

Classification of Rodenticide Poisons

See **Table 17.19**.

Clinical Features

Yellow phosphorous poisoning

- In the first 24 hours postingestion, patients present with mild symptoms such as nausea and vomiting due to gastrointestinal irritation.
- In the next 24–72 hours, patients may remain asymptomatic. There may be a rise in bilirubin levels and liver enzymes at this stage.
- After 72 hours, they can manifest with acute liver failure (ALF), coagulopathy, hypotension, cardiac arrhythmias, and acute kidney injury. Central nervous system involvement occurs as confusion, psychosis, hallucinations, and coma.

TABLE 17.19: Classification of rodenticide poisons.

Highly toxic agents	*Moderately toxic agents*	*Less toxic agents*
LD_{50} 0–50 mg/kg body weight ➢ Strychnine ➢ Thallium ➢ Elemental phosphorus ➢ Metal phosphides ➢ Sodium monofluoroacetate ➢ Arsenic	LD_{50} 50–500 mg/kg ➢ Alpha-naphthylthiourea ➢ Cholecalciferol	LD_{50} >500 mg/kg ➢ Warfarin ➢ "Superwarfarins" or "long-acting" anticoagulant rodenticides (LAARs)—brodifacoum, bromadiolone, chlorophacinone, difenacoum, and diphacinone ➢ Bromethalin ➢ Red squill

Aluminum and zinc phosphide poisoning

- Early features include nausea, vomiting, and epigastric pain due to the corrosive nature of phosphides.
- There may be a garlic odor in the breath of these patients.
- Phosphine gas emitted from emesis and feces of affected.
- These features are rapidly followed by circulatory collapse, hypotension, myocarditis, pericarditis, acute pulmonary edema, and congestive heart failure.

Coumarins

- The evidence of coagulopathy occurs 24–48 hours post-consumption once all the coagulation factors are depleted below 30% of normal.
- Mild-to-severe life-threatening hemorrhage can occur, which include mucocutaneous, gastrointestinal, genitourinary, and intracranial bleeds.
- These include epistaxis, hematuria, gastrointestinal bleeding, spontaneous ecchymoses, and hematomas.
- Intracranial bleeds are associated with a high mortality.
- Paradoxical thrombosis has also been reported following LAAR toxicity. This has been attributed to depletion of protein C and S.

Management of Rodenticide Poisoning

- If there has been no bleeding, but the PT is prolonged, give vitamin K_1 10–50 mg orally two to four times a day
- For prolonged PT with less severe bleeding, give vitamin K_1 10–15 mg SC or IM
- In severe hemorrhage with prolonged prothrombin time (PT) give vitamin K_1 (phytomenadione) 20 mg by slow IV injection
- In severe bleeding, it may be necessary to give fresh frozen plasma, cryoprecipitate or fresh blood.
- N-acetylcysteine (NAC) has been used
- Extracorporeal membrane oxygenation (ECMO)
- Liver transplantation

Copper Sulfate Poisoning

Q. Discuss the clinical feature and management of copper sulfate poisoning.

- Used as insecticide (blue color copper sulfate crystals)
- The clinical features of copper sulfate poisoning include erosive gastropathy (hematemesis and melena), intravascular hemolysis, methemoglobinemia, hepatitis, acute kidney injury and rhabdomyolysis.
- The management of copper sulfate:
  - Reducing absorption—dilution and neutralizing with milk
  - Chelation therapy—penicillamine/BAL
  - Methemoglobinemia is treated with methylene blue
  - Supportive therapy—transfusion, hemodialysis, hyperbaric oxygen.

Q. What is the usual fatal dose of common poisons?

Usual fatal dose of common toxic agents are discussed in **Table 17.20**.

TABLE 17.20: Usual fatal dose of common toxic agents.

Acetyle salicylic acid (Aspirin): 15–20 g
Acids (Mineral): 10–15 mL
Aconite (Root): 1 g
Aluminium phosphide: 500 mg
Arsenic trioxide: 250 mg
Atropine: 10 mg
Long-acting Barbiturate: 3 g
Short-acting Barbiturate: 1–2 g
Benzene: 15–20 mL
Carbolic acid (Phenol): 20 mL
Castor: 5–10 seeds
Cocaine: 1–2 g
Copper sulfate: 30 g
Curare: 60 mg
Cyanide (salt): 200–300 mg
Datura: 50–75 seeds
DDT: 15–30 g
Diazinon: 1 g
Ethanol: 5–8 gm/kg
Ethylene glycol: 100 mL
Formaldehyde: 30–60 mL
Heroin: 50 mg
Iron: 200 mg/kg
Isopropanol: 200–250 mL
Lead acetate: 20 g
Linane: 15–30 g
Malathion: 1 g
Mercuric chloride: 1–2 g
Methanol: 60–250 mL
Morphine: 200 mg
Nicotine: 60 mg
Oleander: 5–15 leaves or 15 gram root
Opium: 500 mg
Organochlorines (except Lindane and DDT): 2–6 g
Oxalic acid: 15–20 g
Paracetamol: 12–20 g
Parathion: 100 mg
Phosphorus: 60–120 mg
Stychnine: 50–100 mg
TEPP: 100 mg
Thallium (salt): 1 g

(DDT: Dichlorodiphenyltrichloroethane; TEPP: Tetraethyl pyrophosphate)

CHAPTER 18

Geriatrics

GERIATRICS

- It is essentially the field of medicine which deals with diseases of the old age.
- Geriatricians are physicians who have special training to better understand the unique needs of older adults, which is why they typically prescribe care for adults 60 and older.
- The United Nations (UN) has agreed for a cutoff of 60+ years to refer to the older population.

GERONTOLOGY

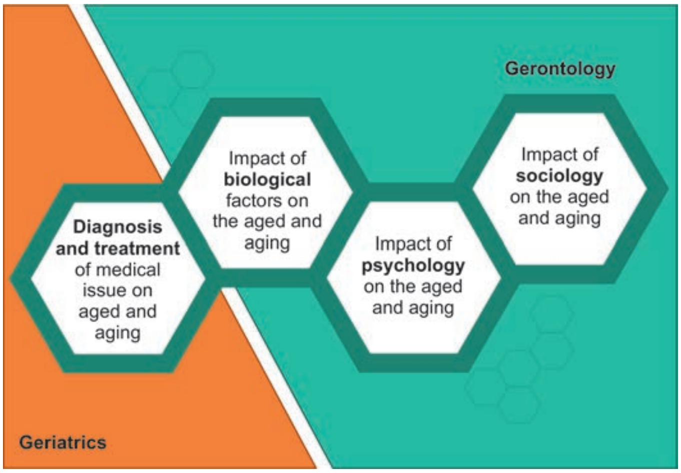
- Gerontology is the study of the phenomenon of aging and its processes and of individuals during their life course.
- It includes the study of social, cultural, psychological, cognitive and biological aspects of aging.

The difference between gerontology and geriatrics has been shown in **Figure 18.1**.

DEMOGRAPHICS OF AGING

Q. IM24.18 Describe the impact of the demographic changes in aging on the population.

Demographic transition: From "pyramid" to "pillar"(Fig. 18.2): In developing countries, the age-sex distribution in populations has been described to be in the form of a pyramid, where the under 5 population is maximum, and the population across age-groups then steadily decreases to a point where it is lowest at the highest age-group of above 75 years. In countries



Gerontology
Impact of **biological** factors on the aged and aging
Impact of **sociology** on the aged and aging
Diagnosis and treatment of medical issue on aged and aging
Impact of **psychology** on the aged and aging
Geriatrics

FIG. 18.1: Difference between gerontology and geriatrics.

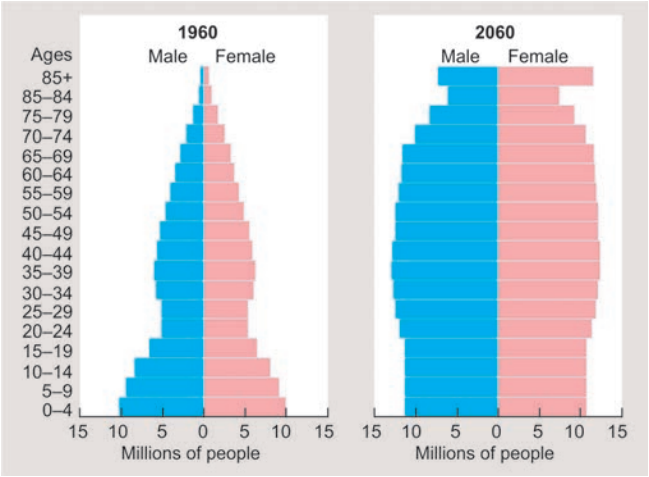


FIG. 18.2: From "pyramid" to "pillar": A century of change.

with improving health care, economic status there is seen a change in the structure of the pyramid to a pillar, wherein the declining fertility rates and decline in mortality rates lead to an increase in the population of older adults. The change from pyramid to a pillar reflects the vastly increased life expectancy and increase in proportion of older adults within the population. Most of the developed countries reflect the age-sex structure of a pillar reflecting declining birth rates and death rates.

Demographic transition reflect a few key trends:

- The vast majority of older adults will be concentrated in developing countries.
- Increase in proportion of elderly females than older men.
- Increase in dependency ratio.
- Women outlive men in most countries.

Impact of demographic transition on health:

Increase in life expectancy leads to:

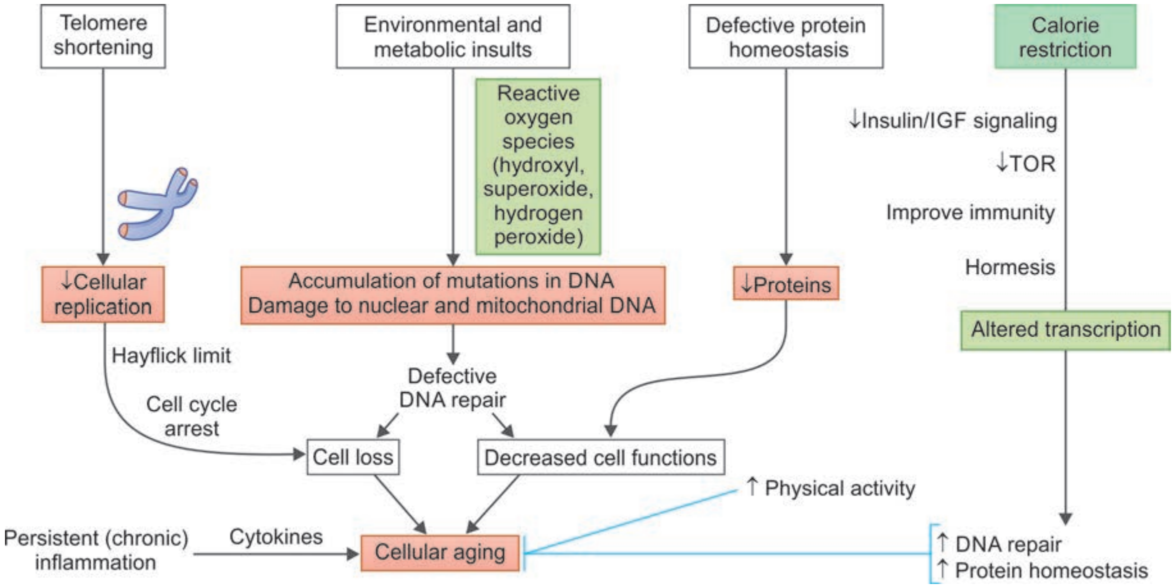
- Increased morbidity, disability and increase in number of older adults living with multiple chronic conditions (such a diabetes, hypertension, stroke, heart disease, arthritis, etc.) leading to burden on healthcare services.
- **Increased need for geriatric services:** There will be an imminent need to create a workforce which is trained to deal with the unique needs of the geriatric population. A need for skilled geriatric care integrating the various disciplines of clinical services with social services will be come essential in the coming decades.

BIOLOGY OF AGING

Aging

Q. What is aging?

Definition: Aging can be defined as a gradual, insidious, and progressive decline in structure and function which begins to unfold after the achievement of sexual maturity. Various mechanisms that cause and counteract cellular aging are shown in **Figure 18.3**.



Telomere shortening
Environmental and metabolic insults
Defective protein homeostasis
Calorie restriction
Reactive oxygen species (hydroxyl, superoxide, hydrogen peroxide)
↓Insulin/IGF signaling
↓TOR
Improve immunity
Hormesis
↓Cellular replication
Accumulation of mutations in DNA Damage to nuclear and mitochondrial DNA
↓Proteins
Altered transcription
Hayflick limit
Cell cycle arrest
Defective DNA repair
Cell loss
Decreased cell functions
↑ Physical activity
Persistent (chronic) inflammation
Cytokines
Cellular aging
↑ DNA repair
↑ Protein homeostasis

FIG. 18.3: Mechanisms of cellular aging and that counteract cellular aging.
(IGF: Insulin-like growth factor; TOR: Target of rapamycin; DNA: Deoxyribonucleic acid)

Theories of Aging

Q. List the common theories of aging.

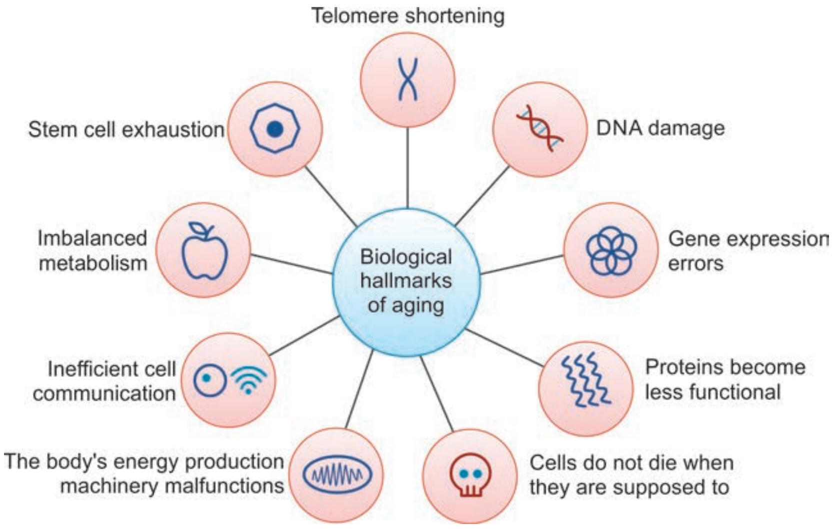
The common theories of aging have been shown in **Table 18.1**.

TABLE 18.1: Common theories of aging.

Stochastic Aging is caused by external forces acting on the body cells and there are ways to slow down the process	**Nonstochastic** Aging is internally regulated by a biological time clock and nothing can change it	**Psychological** Attempt to explain behavior, roles and relationships in the aging process
Free radical theory Cells and damaged by free radicals which lead to aging	**Programmed aging theory** A biological clock controls cell behavior and lifespan	**Disengagement theory** Older adults and society mutually withdraw from each other. The aging person becomes more introspective and self-focused
Somatic mutation theory Chromosomes are damaged by exposure to toxins or radiation	**Pacemaker theory** Neurochromosomes (brain) regulated development and aging throughout the lifespan	**Activity theory** Continuing the social activities of middle age or those activities must be replaced with others for successful aging
Wear and tear theory Damage from everyday wear eventually exceeds the body's ability to repair itself	**Immunological theory** Changes in the immune system are responsible for the effects of aging	**Continuity theory** Personality and behavior develop over a lifetime and are key to how a person adjusts to aging

Remember, no single theory has been accepted to be fully satisfactory.

The biological hallmarks of aging have been shown in **Figure 18.4.**



Telomere shortening
Stem cell exhaustion
DNA damage
Imbalanced metabolism
Biological hallmarks of aging
Gene expression errors
Inefficient cell communication
Proteins become less functional
The body's energy production machinery malfunctions
Cells do not die when they are supposed to

FIG. 18.4: Biological hallmarks of aging.

Q. IM24.1 Describe and discuss the epidemiology, pathogenesis, clinical evolution, presentation and course of common diseases in the elderly.

Q. Describe health problems of aged population.

Changes in Physiologic Function with Age

The changes in physiologic function with age have been shown in **Table 18.2**.

TABLE 18.2: Changes in physiologic function with age.

Organ system	***Age-related changes***
Cardiovascular	➢ Impaired contractile function and baroreceptor function ➢ Decreased conductivity and ventricular filling ➢ Increased systolic blood pressure
Respiratory	➢ Decreased lung elasticity, decreased maximal breathing capacity, decreased number of cilia and diminished mucus clearance, decreased arterial PO_2 ➢ Diminished cough reflex and diminished number of functional alveoli
Gastrointestinal	Decreased esophageal and colonic motility
Renal	➢ Decreased renal blood flow and glomerular filtration rate ➢ Kidney size decreases by 20–30% by age 90
Bladder	Decline in bladder capacity from about 500–600 to about 250 mL

Contd...

Contd...

Organ system	*Age-related change*
Immune	➢ Decreased cell-mediated immunity, decreased T-cell number, decreased T-helper cells ➢ Increased T-suppressor cells, increased autoimmunity ➢ Loss of memory cells ➢ Decline in antibody titers to known antigens
Endocrine	➢ Decreased hormonal responses to stimulation and decreased androgens and estrogens ➢ Impaired glucose tolerance and impaired norepinephrine responses
Autonomic nervous	➢ Impaired response to fluid deprivation ➢ Decline in baroreceptor reflex ➢ Increased susceptibility to hypothermia
Neurologic	➢ Decreased vibratory sense and decreased proprioception ➢ Slowed neuronal transmission
Special senses	➢ Presbyopia ➢ Lens opacification ➢ Decreased hearing, taste, and smell
Musculoskeletal	Sarcopenia (reduced muscle mass and contractile force)
Integumentary changes	➢ Decreased skin elasticity-wrinkling, senile purpura ➢ Increased dryness ➢ Thickened nails ➢ Thinning of hair (baldness) ➢ Decreased subcutaneous fat

Factors which make assessment/treatment of elderly different are presented in **Box 18.1**.

Box 18.1: What makes the assessment/treatment of elderly different?

- Individuals become more dissimilar as they grow
- Abrupt decline in any system is always due to disease and not due to normal aging
- Multiple pathology
- Missing symptoms (e.g., angina in an elderly patient with osteoarthritis—may not manifest)
- Masking symptoms (e.g., history of fall and fracture neck of femur in an elderly female-masked a coexistent hemiparesis due to an internal capsule infarct)

Atypical Disease Presentations in Older Adults

Atypical disease presentations in older adults have been shown in **Table 18.3**.

TABLE 18.3: Atypical disease presentations in older adults.

Diagnosis	*Potential presenting symptoms and signs*	*Diagnosis*	*Potential presenting symptoms and signs*
Myocardial infarction	➢ Altered mental status ➢ Fatigue ➢ Fever ➢ Functional decline	Malignancy	➢ Altered mental status ➢ Fever ➢ Pathologic fracture
Infection	➢ Altered mental status ➢ Functional decline ➢ Hypothermia	Pulmonary embolus	➢ Altered mental status ➢ Fatigue ➢ Fever ➢ Syncope
Hyperthyroidism	➢ Altered mental status ➢ Anorexia ➢ Atrial fibrillation ➢ Chest pain ➢ Constipation ➢ Fatigue ➢ Weight gain	Vitamin deficiency	➢ Altered mental status ➢ Ataxia ➢ Dementia ➢ Fatigue
Depression	➢ Cognitive impairment ➢ Failure to thrive ➢ Functional decline	Fecal impaction	➢ Altered mental status ➢ Chest pain ➢ Diarrhea ➢ Urinary incontinence
Electrolyte disturbance	➢ Altered mental status ➢ Falls ➢ Fatigue ➢ Personality changes	Aortic stenosis	➢ Altered mental status ➢ Fatigue

TABLE 18.4: Systematic comprehensive geriatric evaluation of an older person.

Medical evaluation PLUS	*Additional assessment*
Standard medical history PLUS	➢ Slow the pace of history taking ➢ Ensure the patient can hear ➢ Obtain collateral history ➢ Ask about functional independence ➢ Ask a full drug history

COMPREHENSIVE GERIATRIC ASSESSMENT

Q. What is comprehensive geriatric assessment (CGA)?

Q. IM24.2 Perform multidimensional geriatric assessment that includes medical, psychosocial and functional components.

- Comprehensive geriatric assessment is a multidimensional, multidisciplinary, diagnostic and therapeutic process conducted to determine the medical, mental, and functional problems of older people with frailty so that a coordinated and integrated plan for treatment and follow-up can be developed **(Table 18.4)**.

  Domains assessed and considered in the multidimensional approach of CGA are shown in **Figure 18.5**.

  Basic activities of daily livings (BADLs) and instrumental activities of daily livings (IADLs) are presented in **Table 18.5**. The Barthel Index of Activities of Daily Living (Barthel Index) and Lawton's Instrumental Activities of Daily Living (IADL) can be used to determine the **functional status**.

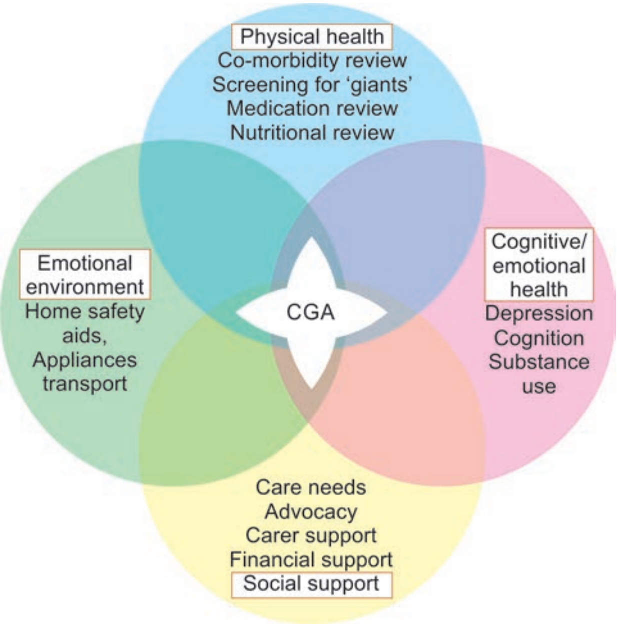


FIG. 18.5: Components of comprehensive geriatric assessment (CGA).

TABLE 18.5: Basic activities of daily livings (BADLs) and instrumental activities of daily livings (IADLs).

Basic activities of daily living	*Instrumental activities of daily living*
BADLS are fundamental activities such as personal cares which are basic to independent living. Loss of BADLs places a heavy burden on the caregivers and is a marker of complete dependence. ➢ Toileting, self-hygiene, bathing, grooming, dressing, feeding, and ambulation (stairs too). ➢ For each of the questions, enquire whether the person can perform it independently, whether he/ she needs assistance or he/ she is completely caregiver dependent	IADLs are complex tasks which enable an older adult to live independently and safely. They are not necessary for fundamental existence in the way that BADLs are necessary, but are an indicator of functional independence. Assessment of IADLs is useful during baseline and follow-up assessments among older adults. Loss of IADLs may be the first indication of deterioration in an older adult. ➢ Complex tasks and roles they do at home ➢ Shopping, meal planning and preparation, housekeeping, laundry, transit, financial management, using a telephone, medication management and driving

- Such assessments may be done by a geriatrician working independently, or as part of an interdisciplinary team that often include specially registered nurses (RNs), occupational therapists (OTs), physical therapists (PTs), social workers (SWs), dietitians, speech language pathologists (SLPs), and specialty pharmacists.

  How to identify elderly patients who would benefit from such an assessment (i.e., the frail elderly)? Strongly consider if they have three or more of the "Red flags" listed in **Box 18.2**. These red flags are indications to do CGA.

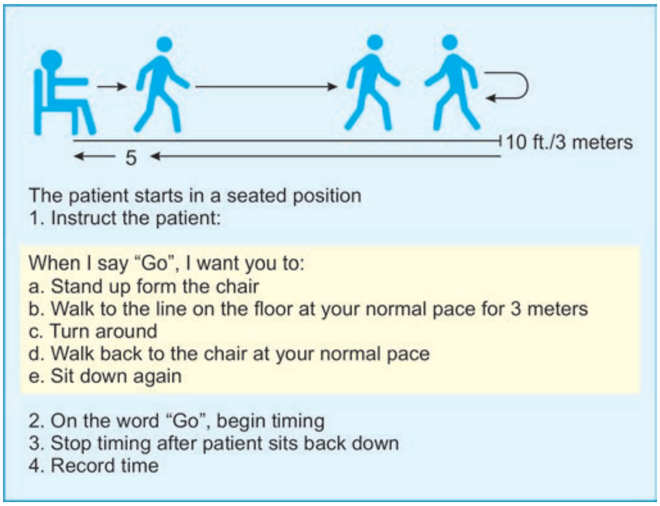
Box 18.2: Indications for doing comprehensive geriatric assessments (Red flags).

- >75 years
- Needs help with BADLs/IADLs by caregiver
- Lives alone
- Falls
- Delirium/confusion
- Incontinence
- >2 admissions to acute care hospital/year
- "Failure to thrive"

COMMON CLINICAL PROBLEMS OF AGING

Geriatric Giants (Fig. 18.7)

- It is a term coined by Sir Bernard Isaacs. He recognized that multiple illness of the senior years needed a broader perspective in socioeconomic and medical terms.



The patient starts in a seated position
1. Instruct the patient:

When I say "Go", I want you to:
a. Stand up form the chair
b. Walk to the line on the floor at your normal pace for 3 meters
c. Turn around
d. Walk back to the chair at your normal pace
e. Sit down again

2. On the word "Go", begin timing
3. Stop timing after patient sits back down
4. Record time

FIG. 18.6: Timed up-and-go test.

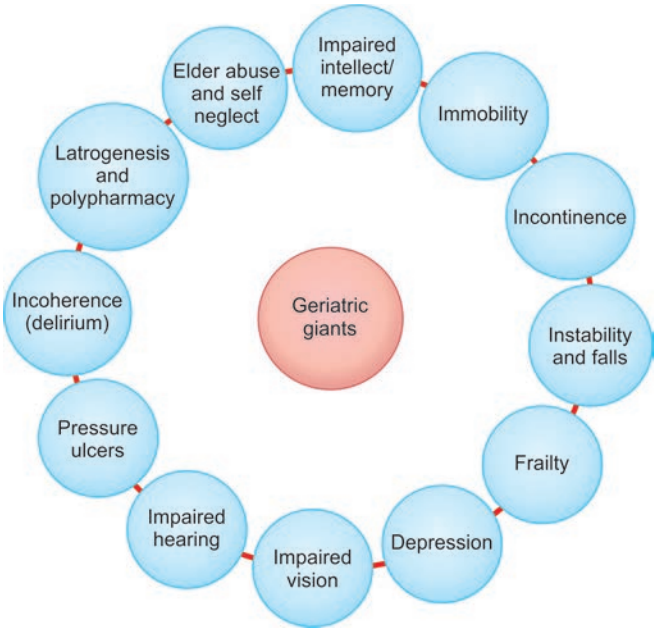


FIG. 18.7: Modern geriatric giants.

- "Geriatric giants" or the four I's:
  1. Immobility
  2. Instability
  3. Incontinence
  4. Impairment of intellect
     - Cognitive impairment
     - Delirium
     - Depression
- Newer geriatric giants
  - Frailty
  - Sarcopenia
  - The "anorexia of aging"
  - Mild cognitive impairment (MCI)
- Giants refer to the principal chronic disabilities of old age that have an impact on physical, mental, and social domains of older adults. Many of these conditions are often wrongly perceived to be an unavoidable part of old age. However, they can be improved.

Dementia

Q. IM24.6 **Describe and discuss the etiopathogenesis causes, clinical presentation, difference in discussion presentation identification, functional changes, acute care, stabilization, management and rehabilitation of dementia in the elderly.**

Dementia is typically progressive and nonreversible. It affects 5–10% of those >65 years and 20–25% >85 years.

- Alzheimer's disease (AD) was the most common type of dementia in India constituting about 45–50%, the prevalence of vascular dementia was found to be 25% in India as against 5% in the West.
- While mean age of dementia patients was around 65 years in India, it was 75 years in the West.
- Hypertension, diabetes, cardiovascular diseases, and stroke are among the chief causes for a higher rate of vascular dementia in India.

Box 18.3: Diagnostic criteria for dementia (DSM-IV).

- Memory impairment: Impaired ability to learn new information or to recall old information.
- One or more of the following:
  - Aphasia (language disturbance)
  - Apraxia (impaired ability to carry out motor activities despite intact motor function)
  - Agnosia (failure to recognize or identify objects despite intact sensory function)
  - Disturbance in executive functioning-impaired ability to plan, organize, sequence, abstract.
- Cognitive deficits result in functional impairment (social/occupational).
- Cognitive deficits do not occur exclusively during a delirium.
- NOT due to other medical or psychiatric conditions.

Diagnostic Criteria for Dementia (DSM-IV) (Box 18.3)

The old dementia terminology required the presence of memory impairment for all of the dementias. It has been recognized that memory impairment is not the first domain to be affected. Hence, DSM-5 has subgrouped neurocognitive disorder into minor or major **(Table 18.6)**.

TABLE 18.6: DSM-5 subgroups of neurocognitive disorder.

Minor neurocognitive disorder (DSM-5)	***Major neurocognitive disorder (DSM-5)***
Modest cognitive decline from a previous level of performance in one or more of the domains	Substantial cognitive decline from a previous level of performance in one or more of the domains
Deficits are insufficient to interfere with independence, but greater effort, compensatory strategies, or accommodation may be required to maintain independence	Deficits are sufficient to interfere with independence
The cognitive deficits do not occur exclusively in the context of a delirium. The cognitive deficits are not primarily attributable to another mental disorder	
Cognitive domains: ➢ **Learning and memory** ➢ **Complex attention** ➢ **Language**	➢ **Perceptual motor** ➢ **Executive function** ➢ **Social cognition**

Mild Cognitive Impairment/Prodromal Dementia

- It is a condition in which there is mild memory impairment alone (1.5 standard deviations below that of age matched controls) in the absence of global cognitive decline or functional disabilities; it can only be diagnosed by sophisticated neuropsychiatric testing. It does not meet criteria for dementia.
- When memory loss predominates, termed amnestic MCI, while if other domains affected with memory being intact its termed nonamnestic MCI.
- Dementia will develop about 30% of those with MCI within 3 years. The remainders have stable, MCIs that do not appear to progress.

Classification of Dementia

- **"Early onset"**—before the age of 60, often familial, more common for frontotemporal dementia (FTD)
  - Strong genetic link
  - Tends to progress more rapidly
- **"Late onset"**—after the age of 60
  - Represents majority of cases
- **Cortical versus subcortical dementia (Table 18.7).**

TABLE 18.7: Characteristic of subcortical dementia and cortical dementia.

Characteristic	***Subcortical dementia***	***Cortical dementia***
Primary functional lesion	Impaired information processing	Domain-specific deficits (aphasia, apraxia, agnosia)
Speed of cognition	Slow	Normal
Memory deficit	Retrieval (recall aided by cues and recognition)	Encoding/storage (poor recognition memory)
Neuropsychiatric symptoms	Apathy, depression	Depression less common
Motor abnormalities	Dysarthria, extrapyramidal	Uncommon, gegenhalten
Pathology	Prominent changes in striatum and thalamus	Prominent changes in cortical association areas
Examples	Huntington's disease, acquired immunodeficiency syndrome (AIDS), dementia complex, progressive supranuclear palsy	Alzheimer's and Creutzfeldt–Jakob disease

Causes of Dementia (Box 18.4)

Box 18.4: Causes of dementia.

Degenerative/inherited

- Alzheimer's disease (60–70%)
- Neurodegenerative disorders: Frontotemporal dementia (including Pick's disease), Lewy body disease, Parkinson's disease, Huntington's disease

Vascular dementia (10–20%): Diffuse small vessel disease

Neoplastic: Primary/secondary deposits

Traumatic: Chronic subdural hematoma, posthead injury

Infections: Creutzfeldt–Jakob disease, human immunodeficiency virus (HIV), syphilis

Toxic/nutritional: Alcohol, thiamine deficiency, vitamin B_{12} deficiency

Prion diseases

Reversible dementia

Modifiable/Reversible Causes of Dementia

The modifiable/reversible causes of dementia have been shown in **Table 18.8**.

Q. List the reversible causes of dementia.

TABLE 18.8: Modifiable causes of dementia.

➢ Depression so-called "Pseudodementia" ➢ Electrolyte disorders (hyponatremia, hypercalcemia, etc.) ➢ Hypothyroidism ➢ Late-onset psychosis ➢ Medication side effects (e.g., sedatives, anticonvulsants, antihypertensives, anticholinergics, first-generation neuroleptics) ➢ Ethanol overuse/misuse	➢ Vitamin deficiencies (B_{12}, folate) ➢ Obstructive sleep apnea ➢ Normal pressure hydrocephalus (reverse with shunting) ➢ Brain tumor (postresection) ➢ Subdural hematoma (SDH) ➢ Subacute CNS infections (i.e., meningitis, encephalitis, syphilis)	Mnemonic—DEMENTIA D = Drugs, Delirium E = Emotions (such as depression) and Endocrine disorders M = Metabolic disturbances E = Eye and Ear impairments N = Nutritional disorders T = Tumors, Toxicity, Trauma to head I = Infectious diseases A = Alcohol, Arteriosclerosis

Alzheimer's Disease

Q. Write a short essay/note on Alzheimer's disease.

Introduction and Definition

- Alzheimer's disease is the most common cause of dementia in the world. It is the most common cause of dementia above the age of 40.
- **In India:** Most common cause of dementia is AD (60–80%) followed by vascular and dementia with Lewy bodies (DLBs).

Etiology

- **Genetic factors**
  - Genetic factors play an important role and about 15% of AD is familial. Familial cases may be of two main groups: (1) early-onset disease with autosomal dominant mode of inheritance and (2) a later-onset group with polygenic inheritance.
  - **Mutations:** It can occur in several genes.
    - Point mutation in **amyloid precursor protein (APP)** can cause AD.
    - Mutations in the gene **presenilin 1 (PS1) and presenilin 2 (PS2)**. PS1 mutations are implicated in over 50% of families with familial AD.
    - The inheritance of one of the alleles of apolipoprotein-ε4 (apo-ε4) is associated with an increased risk of AD.
- **Environmental risk factors**
  - **Age:** If is the main risk factor and incidence of AD increases exponentially with age.
  - **Female gender** may also be a risk factor independent of the greater longevity of women.
  - **Head trauma and vascular risk factors.**
  - According to some studies, long-term consumption of **NSAIDs** and acetaminophen has shown protection.

Pathology

- Biochemically characterized by a deficiency of acetylcholine, with cortex, amygdala, hippocampus all affected.
- Basal nucleus of Meynert depleted of acetylcholine-containing neurons.
- In minority of cases, there is an autosomal dominant inheritance linked to chromosomes 1, 14, or 21 (early onset).
- Apolipoprotein E gene, coded on chromosome 19, when homozygous for allele E4, increases the risk for late-onset AD.

Clinical Features

Q. Write a short essay/note on clinical features of Alzheimer's disease.

The main clinical features are:

- **Memory impairment/loss:** Early recent (short-term) memory loss is key feature of AD.
- **Language problem:** It is the next common symptom, common being anomia and difficulty with word finding is characteristic.
- **Apraxia:** It is impaired ability to carry out skilled, complex, organized motor activities.
- **Agnosia:** It is failure to recognize familiar objects (e.g., clothing, places or people).
- **Frontal executive function:** It is impairment of organizing, planning, and sequencing.
- **Parietal presentation:** Visuospatial difficulties and difficulty with orientation in space.
- **Myoclonic jerks** (sudden brief contractions of various muscles or the whole body) may occur spontaneously or in response to physical or auditory stimulation. This phenomenon raises the possibility of Creutzfeldt–Jakob disease (CJD), but the course of AD is much more prolonged.
- **Generalized seizures** may also occur.
- Death usually results from malnutrition, secondary infections, or heart disease.
- The typical duration of AD is 8–10 years, but the course can range from 1 to 25 years.
- Course of the disease
  - **Mild** [Mini-Mental State Examination (MMSE) 20–24]—primarily memory and visuospatial deficits, mild executive functioning impairment.
  - **Moderate** (MMSE 11–20)—more pronounced aphasia, apraxia, loss of IADLs, may need increased assistance with BADLs, often exhibiting neuropsychiatric symptoms.
  - **Severe** (MMSE 0–10)—severe language disturbances, pronounced neuropsychiatric manifestations, neurological symptoms (rigidity, incontinence, dysphagia, gait disturbance).
  - **Death** 8-12 years after the diagnosis.

- **Institutionalization** common with increasing neuropsychiatric symptoms, loss of BADLs, caregiver stress.

Diagnostic Criteria for Alzheimer's Disease

The diagnostic criteria for AD have been shown in **Box 18.5**.

Box 18.5: Diagnostic criteria for Alzheimer's disease.

- Memory impairment
- One or more of the following:
  - Aphasia
  - Apraxia
  - Agnosia
  - Disturbance in executive functioning.

Investigations

Investigation is aimed at excluding other treatable causes of dementia.

- Neuroimaging studies [computed tomography (CT) and magnetic resonance imaging (MRI)] are not specific for AD and may be normal early in the course of the disease. As AD progresses, diffuse cortical atrophy becomes apparent, and detailed MRI scans show atrophy of the hippocampus.
- Positron emission tomography (PET) scan: It is the test of choice. It shows hypoperfusion in bilateral perietotemporal cortex.
- Cerebrospinal fluid (CSF) markers: (1) raised tau proteins, (2) low beta-42 amyloid, and (3) elevated ceramide level.
- Routine investigations: Blood chemistry, a complete blood count, tests for syphilis, serum levels of vitamin B_{12}, and thyroid functions.

Treatment for Alzheimer's Disease

There is no specific treatment and the primary focus is on long-term amelioration of associated behavioral and neurologic problems.

Drugs used (Table 18.9): Donepezil, rivastigmine, galantamine, and tacrine are cholinesterase inhibitors. Patients with AD have reduced cerebral content of choline acetyltransferase, which leads to a decrease in acetylcholine synthesis and impaired cortical cholinergic function.

- Memantine appears to act by blocking overexcited N-methyl-D-aspartate (NMDA) channels.
- Statins may have protective effect on dementia especially vascular. Antioxidants (vitamin E, selegiline), estrogen replacement, *Ginkgo biloba* have been tried.
- Mild-to-moderate depression is common in the early stages of AD and responds to antidepressants. Selective serotonin reuptake inhibitors (SSRIs) are commonly used due to their low anticholinergic side effects.
- Recommend psychotherapy, exercise, pleasurable activities, support groups, memory aids.
- Minimize changes in caregivers/environment.
- Music therapy is gaining strength as evidence-based intervention for treatment of anxiety.

TABLE 18.9: Drugs used for Alzheimer's disease and their adverse reactions.

Donepezil	Initial dose 5 mg at bedtime Titrate to 10 mg once daily at 4–6 weeks For moderate to severe dementia, may titrate to 23 mg at 3 months	Nausea, vomiting, diarrhea, muscle cramps
Galantamine	Initial dose 4 mg twice a day Titrate to 8 mg twice a day at 4 weeks Titrate to 12 mg twice a day at 4 weeks	Nausea, vomiting, agitation, sleep disturbances
Rivastigmine	Initial dose 1.5 mg twice daily for 2 weeks Increase in increments of 1.5 mg twice daily every 2 weeks if well tolerated Maximum dose 12 mg a day	Nausea, vomiting, diarrhea, headache, dizziness
Memantine N-methyl-D-aspartate (NMDA) receptor antagonist—glutamate receptor antagonist	Initial dose 5 mg daily, at 1-week increase to 5 mg twice a day, in another week increase to 5 mg in the morning and 10 mg in the evening, and in another week increase to target dose of 10 mg twice a day	Dizziness, confusion, hallucination, agitation
Other drugs available ➢ **Selegiline**—selective monoamine oxidase B (MAO-B) inhibitor (10 mg/day) ➢ **Vitamin E (alpha-tocopherol)**—2,000 international units/day ➢ Citicoline ➢ Cerebrolysin ➢ Estrogen replacement ➢ *Ginkgo biloba* ➢ Statins	**Newer developmental agents:** ➢ Immunization against β-amyloid ➢ Huprine X—acetylcholinesterase inhibitor ➢ Xanomeline patch—M1/M4 muscarinic receptor agonist ➢ AIT-082 (purine hypoxanthine derivative)—increases neurotransmission ➢ Cyclooxygenase-2 (COX-2) inhibitors—neuroinflammation therapy ➢ Protease inhibitors—target gamma-secretases to prevent amyloid formation	

Note: Do not routinely prescribe or continue acetylcholineterase inhihitors or NMDA antagonists in patients with advanced dementia.

Vascular Dementia (Multi-infarct Dementia)

Q. Discuss the clinical features of vascular dementia.

- Second most common cause of dementia. Found in 15–30% of patients with dementia.
- **Risk factors:** Male sex, advanced age, diabetes, hypertension and/or other cardiovascular disorders.

- **Abrupt onset** of symptoms followed by **stepwise deterioration**.
- Findings on neurologic examination consistent with prior stroke(s), infarcts on cerebral imaging.
- **Focal neurologic symptoms:** Pseudobulbar palsy, dysarthria, and dysphagia are most common.

NINDS-AIREN Criteria for Vascular Dementia

All the following criteria should be present:

- Dementia
- Focal signs on examination + evidence of cerebrovascular disease by CT or MRI.

A relationship of the two above, with dementia within 3 months of a recognized stroke and/or abrupt deterioration in fluctuation, or fluctuating stepwise progression of cognitive deficits.

Physical examination

- May show increased tone (especially in the legs), exaggerated deep tendon reflexes, and Babinski responses.
- Examination may reveal carotid bruits, fundoscopic abnormalities, and enlarged heart.
- Gait apraxia ("magnetic" gait) may be seen.
- MRI may reveal hyperintensities and focal atrophy suggestive of old infarctions.

Treatment

- Control of risk factors such as hypertension, smoking, diabetes, hyperlipidemia
- Antiplatelets/statins
- Correction of sources of emboli, endarterectomy, and anticoagulant therapy

Box 18.6: Types of vascular cognitive impairment.

- Vascular cognitive impairment, no dementia (VCIND)
- Vascular dementia (VaD)
  - Poststroke dementia (PSD), defined as dementia manifesting within 6 months after a stroke
  - Subcortical ischemic vascular dementia (SIVaD)
  - Multi-infarct (cortical) dementia
- Mixed vascular cognitive impairment (VCI) plus Alzheimer's disease (AD)

Types of Vascular Cognitive Impairment

The types of vascular cognitive impairment have been shown in **Box 18.6**.

Frontotemporal Dementia

Q. Write short essay on the clinical features of frontotemporal dementia.

- Characterized by focal atrophy of the frontal and temporal lobes in the absence of Alzheimer's pathology.
- **Pick's disease** was the first recognized subtype of FTD, one that is characterized pathologically by the presence of Pick's bodies (silver staining intracytoplasmic inclusions) in the neocortex and hippocampus.
- Clinically, presents initially with **language abnormalities** and **behavioral disturbances**.
- Occurs between the ages of 35 and 75 years, and only rarely after age 75; the mean age of onset is the 6th decade.
- Both sexes are equally affected.
- **"Walnut brain"**—as there is profound loss of matter in the frontal lobes, to a slightly lesser degree in the temporal lobes, in comparison with relatively preserved parietal and occipital lobes.

Genetics of Frontotemporal Dementia

- About 45% of patients have a family member affected.
- Up to 18% of these have an abnormality on the short arm of chromosome 17 localized near gene for the microtubule-associated protein, *tau*.

Box 18.7 lists the core diagnostic features and **Table 18.10** lists the supportive diagnostic features of FTD.

Box 18.7: Core diagnostic features of frontotemporal dementia (FTD).

- Insidious onset and gradual progression
- Early decline in social interpersonal conduct
- Early impairment in regulation of personal conduct
- Early emotional blunting
- Early loss of insight

TABLE 18.10: Supportive diagnostic features of frontotemporal dementia.

Behavioral disorder	***Speech and language deficits***
➢ Decline in personal hygiene and grooming ➢ Mental rigidity and inflexibility ➢ Distractibility and impersistence ➢ Utilization behavior hyperorality and dietary changes ➢ Perseverations and stereotyped behavior	➢ Altered speech output (aspontaneity and economy of speech) ➢ Stereotype speech ➢ Echolalia ➢ Perseverations ➢ Mutism
Physical signs	***Investigations***
➢ Primitive reflexes; at least one of grasp, snout and sucking ➢ Incontinence ➢ Akinesia, rigidity and tremor (rarely) ➢ Low and labile blood pressure	➢ **Neuropsychology:** Significant impairment on frontal lobe tests in the absence of severe amnesia, aphasia or perceptuospatial disorder ➢ Electroencephalography (**EEG): **Normal despite clinically evident dementia ➢ **Brain imaging** (structural or functional) predominant frontal and/or temporal abnormality

Dementia with Lewy Bodies

- Most common dementia syndrome associated with parkinsonism.
- Second most common form of neurodegenerative dementia after AD.
- For a probable diagnosis **(Box 18.8)** of Lewy body disease, need at least two of the following:
  - Fluctuating cognition with pronounced variations in attention and alertness.
  - Recurrent visual hallucinations which are typically well-formed and detailed.
  - Spontaneous motor features of parkinsonism.

Box 18.8: Features supporting the diagnosis of dementia with Lewy bodies.

- Syncope or transient loss of consciousness (LOC)
- Neuroleptic sensitivity (i.e., new shuffling gait, tardive dyskinesia)
- Systematized delusions
- Hallucinations in other modalities (i.e., smell, hearing, taste)
- Falls

Parkinson's Disease

- **Cardinal motor features**
  - Bradykinesia and akinesia
  - Rigidity
  - Resting tremor
  - Postural instability
- Dementia typically occurs in the last half of the clinical course of Parkinson's disease, whereas it is often one of the presenting features of DLB.

Pick's Disease and Creutzfeldt–Jakob Disease

Salient features of Pick's disease and CJD are presented in **Table 18.11**.

TABLE 18.11: Salient features of Pick's disease and Creutzfeldt–Jakob disease.

Pick's disease	***Creutzfeldt–Jakob disease***
➢ Subtype of frontal lobe dementia ➢ Pick bodies (silver staining intracytoplasmic inclusions in neocortex and hippocampus) ➢ Language abnormalities ➢ Logorrhea (abundant unfocused speech) ➢ Echolalia (spontaneous repetition of words/phrases) ➢ Palilalia (compulsive repetition of phrases)	➢ Rapid onset and deterioration ➢ Motor deficits ➢ Seizures ➢ Slowing and periodic complexes on EEG ➢ Myoclonic activity

Normal Pressure Hydrocephalus

It is a condition of pathologically enlarged ventricular size with normal opening pressures on lumbar puncture, clinically presents with a triad of dementia, gait disturbance, and urinary incontinence **(Adams triad**—"wet, wobbly, and wacky" triad) reversible by the placement of a ventriculoperitoneal shunt.

Cognitive Testing

- **Mini-mental state examination** tests a broad range of cognitive functions including orientation, recall, attention, calculation, language manipulation, and constructional praxis. Scores can be classified as: no cognitive impairment = 24–30; MCI = 18–23; severe cognitive impairment = 0–17.
- **Montreal cognitive assessment (MoCA)** is a 30-point test that is more sensitive for the detection of MCI, and it includes items that sample a wider range of cognitive domains, including memory, language, attention, visuospatial, and executive functions.
- **Mini-Cog** combines clock drawing and three item memory test.
- **Saint Louis University Mental Status (SLUMS)** examination.

Delirium in the Elderly (Fig. 18.8 and Flowchart 18.1)

Q. IM24.3 Describe and discuss the etiopathogenesis, clinical presentation, identification, functional changes, acute care, stabilization, management and rehabilitation of acute confusional states.

Definition: It is an acute syndrome of transient, reversible cognitive dysfunction *(details discussed in Chapter 20)*.

Management

Prevention is the best medicine

Nonpharmacologic measures:

- Eliminate extra medications, reverse metabolic abnormalities, hydration, and nutrition
- Education of patients and family
- Reorientation by staff, family, sitters, clocks, calendars
- Remove nonessential lines and tubes

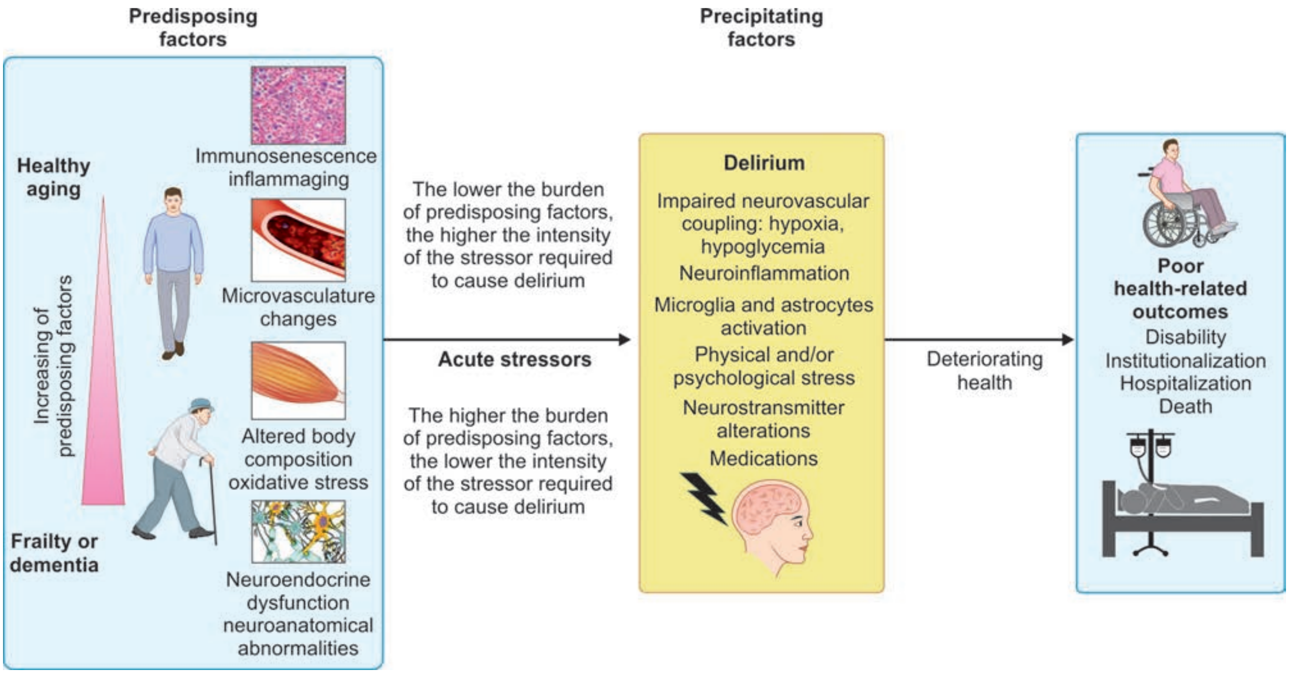
Pharmacologic measures:

- Drug therapy:
  - Delirium that causes injury to the patient or others should be treated with medications
  - The most common medications used are neuroleptics (haloperidol, risperidone, olanzapine)
  - Benzodiazepines (lorazepam) often are used for withdrawal states
  - Thiamine, cyanocobalamin supplementation

Depression

Q. IM24.5 Describe and discuss the etiopathogenesis, clinical presentation, identification, functional changes, acute care, stabilization, management and rehabilitation of depression in the elderly.

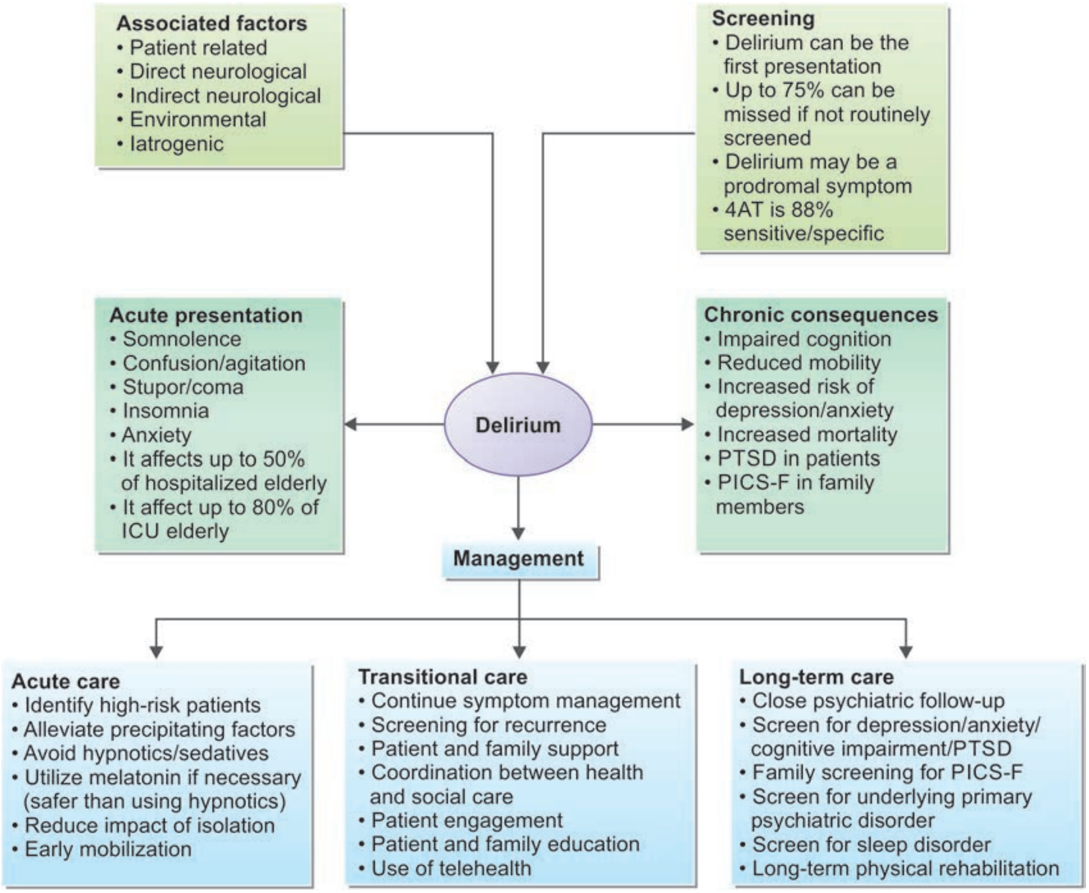
- Depression is the most common psychiatric illness in the elderly. Although common, it is not a natural part of aging.



Predisposing factors
Healthy aging
Increasing of predisposing factors
Frailty or dementia
Immunosenescence inflammaging
Microvasculature changes
Altered body composition oxidative stress
Neuroendocrine dysfunction neuroanatomical abnormalities
The lower the burden of predisposing factors, the higher the intensity of the stressor required to cause delirium
Acute stressors
The higher the burden of predisposing factors, the lower the intensity of the stressor required to cause delirium
Precipitating factors
Delirium
Impaired neurovascular coupling: hypoxia, hypoglycemia
Neuroinflammation
Microglia and astrocytes activation
Physical and/or psychological stress
Neurostransmitter alterations
Medications
Deteriorating health
Poor health-related outcomes
Disability
Institutionalization
Hospitalization
Death

FIG. 18.8: Predisposing and precipitating factors leading to delirium after an acute stressor, and hesitating in poor health-related outcomes.

FLOWCHART 18.1: Management of delirium.



Associated factors
- Patient related
- Direct neurological
- Indirect neurological
- Environmental
- Iatrogenic

Screening
- Delirium can be the first presentation
- Up to 75% can be missed if not routinely screened
- Delirium may be a prodromal symptom
- 4AT is 88% sensitive/specific

Delirium

Acute presentation
- Somnolence
- Confusion/agitation
- Stupor/coma
- Insomnia
- Anxiety
- It affects up to 50% of hospitalized elderly
- It affect up to 80% of ICU elderly

Chronic consequences
- Impaired cognition
- Reduced mobility
- Increased risk of depression/anxiety
- Increased mortality
- PTSD in patients
- PICS-F in family members

Management

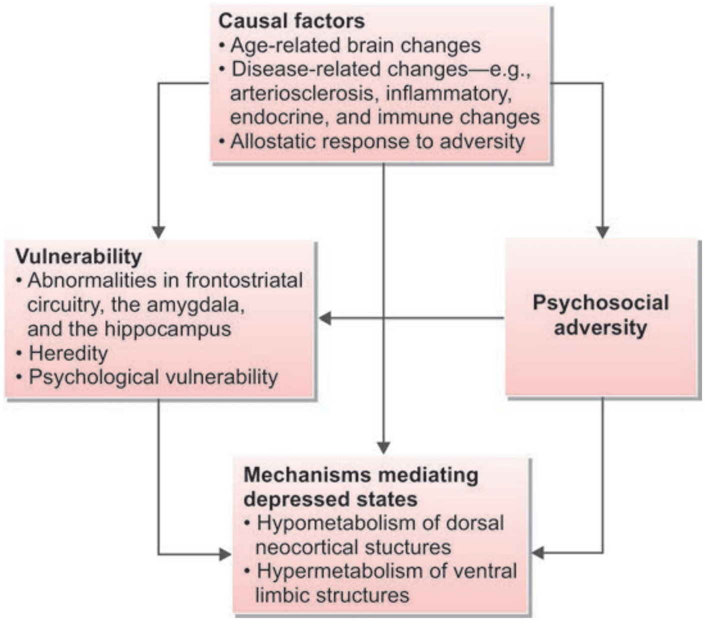
Acute care
- Identify high-risk patients
- Alleviate precipitating factors
- Avoid hypnotics/sedatives
- Utilize melatonin if necessary (safer than using hypnotics)
- Reduce impact of isolation
- Early mobilization

Transitional care
- Continue symptom management
- Screening for recurrence
- Patient and family support
- Coordination between health and social care
- Patient engagement
- Patient and family education
- Use of telehealth

Long-term care
- Close psychiatric follow-up
- Screen for depression/anxiety/cognitive impairment/PTSD
- Family screening for PICS-F
- Screen for underlying primary psychiatric disorder
- Screen for sleep disorder
- Long-term physical rehabilitation

(PTSD: Post-traumatic stress disorder; PICS-F: Post-intensive care syndrome-family)

FLOWCHART 18.2: Pathophysiology of depression in elderly.



Causal factors
• Age-related brain changes
• Disease-related changes—e.g., arteriosclerosis, inflammatory, endocrine, and immune changes
• Allostatic response to adversity
Vulnerability
• Abnormalities in frontostriatal circuitry, the amygdala, and the hippocampus
• Heredity
• Psychological vulnerability
Psychosocial adversity
Mechanisms mediating depressed states
• Hypometabolism of dorsal neocortical stuctures
• Hypermetabolism of ventral limbic structures

TABLE 18.12: Characteristics of depression, delirium, and dementia.

	Depression	*Delirium*	*Dementia*
Onset	Weeks to months	Hours to days	Months to years
Mood	Low/apathetic	Fluctuates	Fluctuates
Course	Chronic; responds to treatment	Acute; responds to treatment	Chronic, with deterioration over time
Self-awareness	Likely to be concerned about memory impairment	May be aware of changes in cognition; fluctuates	Likely to hide or be unaware of cognitive deficits
Activities of daily livings (ADLs)	May neglect basic self-care	May be intact or impaired	May be intact early, impaired as disease progresses
Instrumental activities of daily livings (IADLs)	May be intact or impaired	May be intact or impaired	May be intact early, impaired before ADLs as disease progresses

- The prevalence in community dwelling elders ranges from 8 to 15%; it raises to as much as 30% of those in long-term care facilities. Depression and suicide are common in the elderly (especially older males; those over 75, have the same risk of suicide as 20–24 years old depressed males) **(Flowchart 18.2)**.
- Depression is NOT present in ALL older adults, but is under recognized and under treated.

Bereavement or grief reaction is commonly misdiagnosed as depression. A normal grief reaction after the death of a spouse or a loved one lasts about 2 months in time, with the mourning process being complete in <2 years. Feelings of sadness and preoccupation with the deceased are not helped by antidepressant medications during this time of mourning.

The characteristics of depression, delirium, and dementia have been shown in **Table 18.12**.

Treatment of depression in the elderly is discussed in Chapter 20.

Incontinence

Involuntary loss of urine or stool in sufficient amount or frequency to constitute a social and/or health problem.

Urinary Incontinence

- Urinary incontinence is defined as the involuntary loss of urine. It is a heterogeneous condition that ranges in severity from dribbling small amounts of urine to continuous urinary incontinence.
- The prevalence increases with age, but it is NOT a part of normal aging. It affects about 25–30% of community dwelling older women and 10–15% of community dwelling older men, 50% of nursing home residents; often associated with dementia, fecal incontinence, inability to walk, and transfer independently.
- **Consequences:**
  - Social stigmata—leads to restricted activities and depression
  - Medical complications—skin breakdown, increased urinary tract infections
  - Institutionalization—urinary incontinence is the second leading cause of nursing home placement.

Box 18.9: Potentially reversible causes.

P—**P**olyuria, **P**haramaceuticals

Reversible Conditions Associated with Urinary Incontinence

Potentially reversible causes of urinary incontinence are listed in **Box 18.9**. Medications causing incontinence are listed in **Box 18.10**.

Categories of Incontinence

- **Urge incontinence:** Other names—detrusor hyperactivity, detrusor instability, irritable bladder, spastic bladder.

  - Most common cause of urinary incontinence >75 years of age.
  - Abrupt desire to void cannot be suppressed.
  - Usually idiopathic.
  - **Causes:** Infection, tumor, stones, atrophic vaginitis or urethritis, stroke, Parkinson's disease, dementia.
- **Stress incontinence:**
  - Most common type in women <75 years old.
  - Occurs with increase in abdominal pressure; cough, sneeze, etc.
  - Hypermotility of bladder neck and urethra; associated with aging, hormonal changes, trauma of childbirth or pelvic surgery (85% of cases).
  - Intrinsic sphincter problems: Due to pelvic/incontinence surgery, pelvic radiation, trauma, neurogenic causes (15% of cases).
- **Overflow incontinence:**
  - Overdistention of bladder.
  - Bladder outlet obstruction; stricture, benign prostatic enlargement (BPH), cystocele, fecal impaction.
  - Noncontractile bladder (hypoactive detrusor or atonic bladder), diabetes, multiple sclerosis, spinal injury, medications.
- **Functional incontinence:**
  - Does not involve lower urinary tract.
  - Result of psychological, cognitive or physical impairment.

A recently defined syndrome, **overactive bladder,** includes urinary frequency (more than eight voids per 24 hours), nocturia (awakening at night from sleep to void), and urgency (the acute need to void), with or without incontinence is prevalent in around 31% women 75 years and older and 42% men 75 years and older.

Falls in the Elderly

Q. IM24.13 Describe and discuss the etiopathogenesis, clinical presentation, identification, functional changes, acute care, stabilization, management and rehabilitation of falls in the elderly.

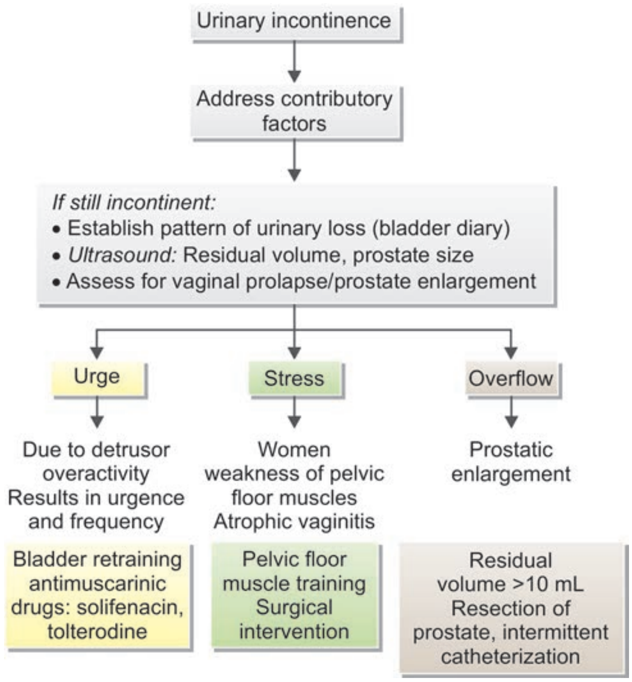
About 30% of individuals over 65 years of age fall each year. About 10–15% of falls result in serious injury and they are the cause of >90% of hip fractures in this age group. Factors causing falls in elderly are listed in **Flowchart 18.4**.

Fall risk factors and targeted interventions have been shown in **Table 18.13**.

Box 18.10: Medications causing incontinence.

- Diuretics
- Anticholinergics: Antihistamines, antipsychotics, antidepressants
- Sedatives/hypnotics
- Alcohol
- Narcotics
- α-adrenergic agonists/antagonists
- Calcium channel blockers

FLOWCHART 18.3: Approach to urinary incontinence.



Urinary incontinence
Address contributory factors
If still incontinent:
• Establish pattern of urinary loss (bladder diary)
• Ultrasound: Residual volume, prostate size
• Assess for vaginal prolapse/prostate enlargement
Urge
Stress
Overflow
Due to detrusor overactivity Results in urgence and frequency
Women weakness of pelvic floor muscles Atrophic vaginitis
Prostatic enlargement
Bladder retraining antimuscarinic drugs: solifenacin, tolterodine
Pelvic floor muscle training Surgical intervention
Residual volume >10 mL Resection of prostate, intermittent catheterization

Treatment Options in Urinary Incontinence (Flowchart 18.3)

General treatment options in urinary incontinence are mentioned in **Box 18.11**.

Pharmacological interventions:

- **Urge incontinence:** Oxybutynin, propantheline, imipramine. Mirabegron has been used for management of overactive bladder in frail older adults.
- **Stress incontinence:** Phenylpropanolamine, pseudoephedrine, estrogen (orally, transdermally or transvaginally).

The multidisciplinary approach to prevent falls has been shown in **Figure 18.9**.

Box 18.11: General treatment options in urinary incontinence.

- Reduce amount and timing of fluid intake
- Avoid bladder stimulants (caffeine)
- Use diuretics judiciously (not before bed)
- Reduce physical barriers to toilet (use bedside commode)
- Bladder training
- Patient education
- Scheduled voiding
- Positive reinforcement
- Pelvic floor exercises (Kegel exercises)
- Biofeedback
- Caregiver interventions: Scheduled toileting, habit training, prompted voiding

Surgical interventions:

- **Urethral hypermotility:** Marshall–Marchetti–Krantz procedure, needle neck suspension.
- **Intrinsic sphincter deficiency:** Sling procedure.

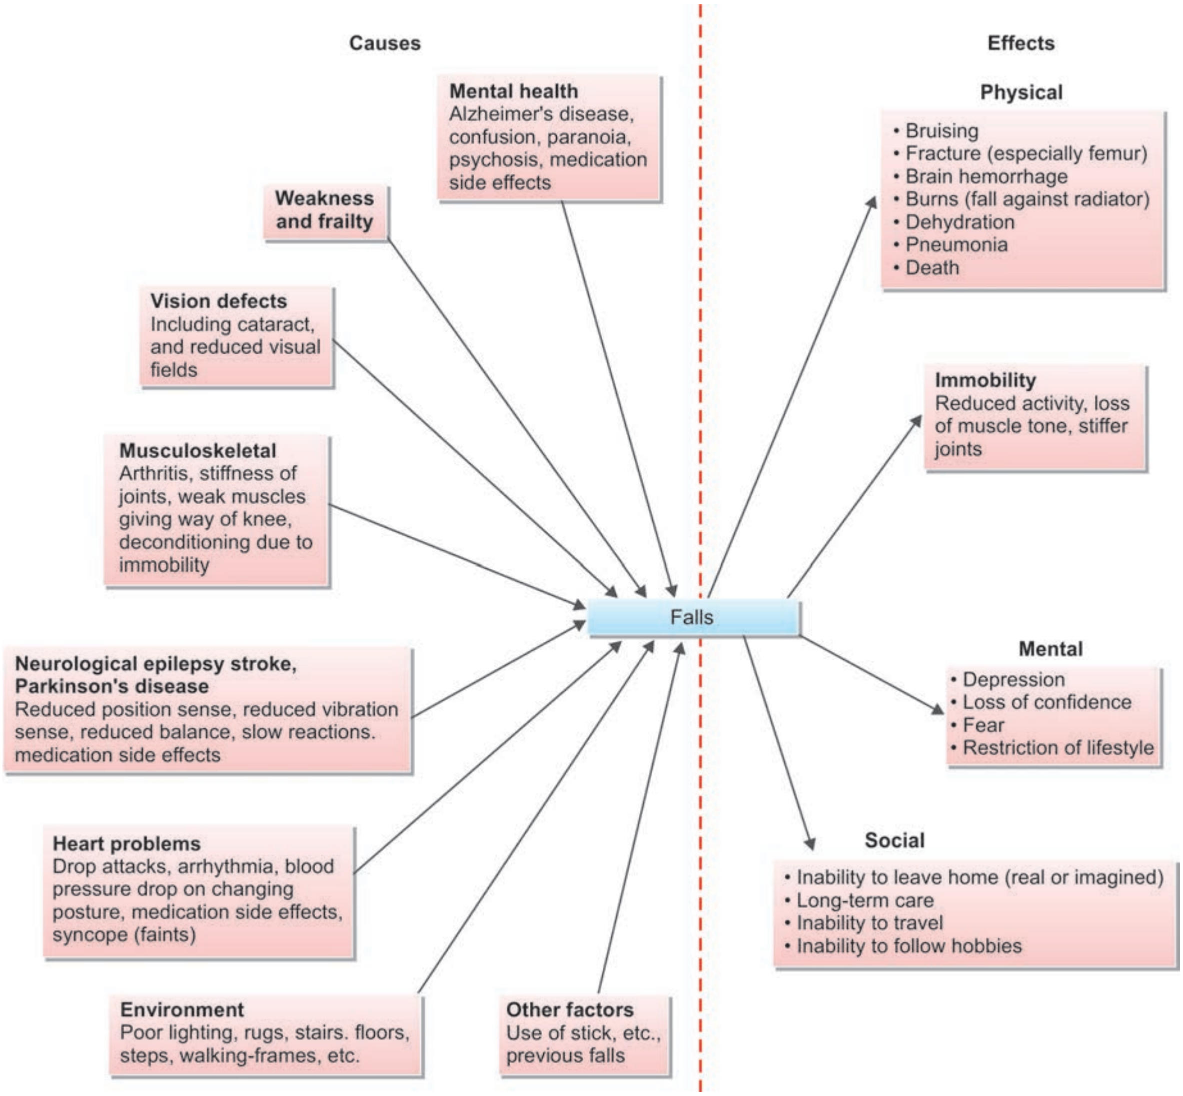
Other interventions:

- Other interventions have been shown in **Box 18.12**.

Box 18.12: Other interventions in urinary incontinence.

- Pessaries
- Periurethral bulking agents (periurethral injection of collagen, fat or silicone)
- Diapers or pads
- Chronic catheterization
  - Perurethral or suprapubic
  - Indwelling or intermittent

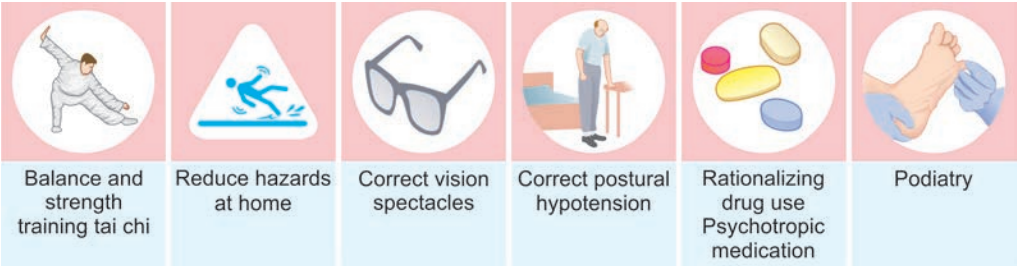
FLOWCHART 18.4: Factors causing falls and their effects in elderly.



Causes
Effects
Mental health
Alzheimer's disease, confusion, paranoia, psychosis, medication side effects
Weakness and frailty
Vision defects
Including cataract, and reduced visual fields
Musculoskeletal
Arthritis, stiffness of joints, weak muscles giving way of knee, deconditioning due to immobility
Neurological epilepsy stroke, Parkinson's disease
Reduced position sense, reduced vibration sense, reduced balance, slow reactions. medication side effects
Heart problems
Drop attacks, arrhythmia, blood pressure drop on changing posture, medication side effects, syncope (faints)
Environment
Poor lighting, rugs, stairs. floors, steps, walking-frames, etc.
Other factors
Use of stick, etc., previous falls
Falls
Physical
• Bruising
• Fracture (especially femur)
• Brain hemorrhage
• Burns (fall against radiator)
• Dehydration
• Pneumonia
• Death
Immobility
Reduced activity, loss of muscle tone, stiffer joints
Mental
• Depression
• Loss of confidence
• Fear
• Restriction of lifestyle
Social
• Inability to leave home (real or imagined)
• Long-term care
• Inability to travel
• Inability to follow hobbies

TABLE 18.13: Fall risk factors and targeted interventions.

Risk factors	***Targeted intervention***
Postural hypotension	Behavioral recommendations, such as hand clenching, elevation of head of bed; discontinuation or substitution of high-risk medications
Use of benzodiazepine or sedative-hypnotic agent	Education about sleep hygiene; discontinuation or substitution of medications
Use of multiple prescription medications	Review of medications
Environmental hazards	Appropriate changes; installation of safety equipment (e.g., grab bars)
Gait impairment	Gait training, assistive devices, balance or strengthening exercises
Impairment in transfer or balance	Balance exercises, training in transfers, environmental alterations (e.g., grab bars)
Impairment in leg or arm muscle strength or limb range of motion	Exercise with resistance bands or putty, with graduated increases in resistance



Balance and strength training tai chi
Reduce hazards at home
Correct vision spectacles
Correct postural hypotension
Rationalizing drug use Psychotropic medication
Podiatry

FIG. 18.9: Multidisciplinary approach to prevent falls.

Frailty

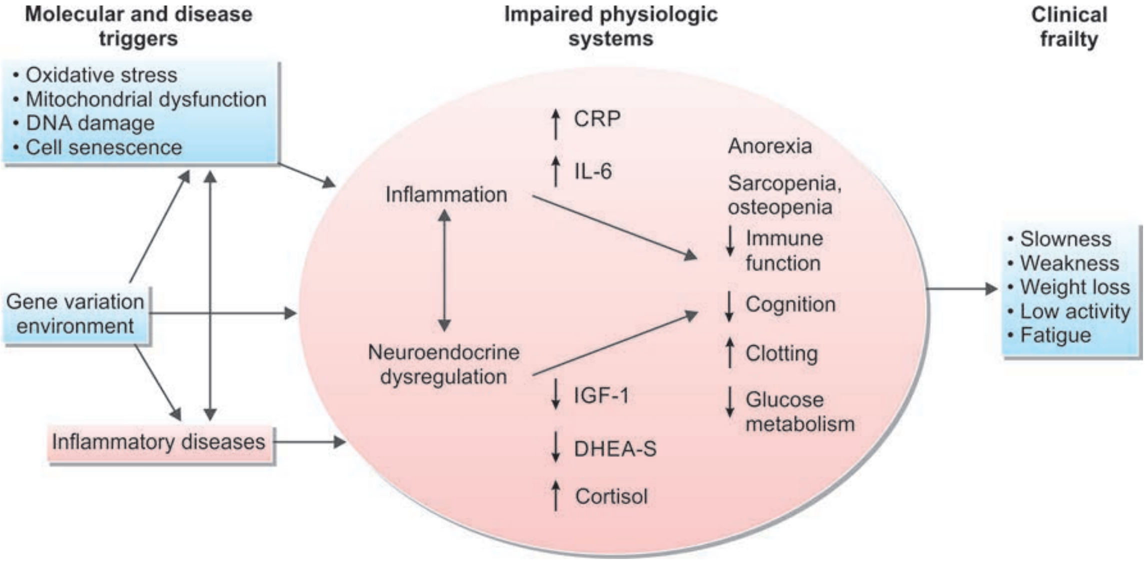
Q. Define frailty. List the diagnostic criteria for frailty.

- Frailty = Loss of reserve
- Defined as the loss of an individual's ability to withstand minor stresses because the reserves in function of several organ systems are severely reduced. **Flowchart 18.5** describes the pathophysiological basis of frailty.
- Physical frailty/phenotypic or syndromic frailty captures the specific signs and symptoms (fatigue, low activity, weakness, weight loss, and slow gait) of older adults who vulnerable to adverse health outcomes.
- Deficit accumulation frailty or index frailty is a conceptual framework that helps identify the frail, vulnerable older adults through cumulative comorbidities and cumulative illnesses as frail.
- Even a trivial illness/adverse drug reaction (ADR) → organ failure/death.
- Characterized by multisystem dysregulation involving four main domains that include: (1) chronic inflammation, (2) sarcopenia, (3) osteoporosis, and (4) alteration in neuroendocrine function.
- **Fried frailty score** non-frail (score 0), pre-frail (score 1–2) and frail (score 3–5).
  - Unintentional weight loss (≥5% of body weight in last year)
  - Self-reported exhaustion (positive response to questions regarding effort required for activity)
  - Weakness (decreased grip strength)
  - Slow walking speed (gait speed) (>6–7 seconds to walk 15 feet)
  - Decreased physical activity (kcals spent per week: males expending <383 kcals and females <270 kcals)

Treatment

- Address the precipitating acute illness
- Address the underlying loss of reserve
- Exercise—improve musculoskeletal function, balance and aerobic capacity
- Medication review and deprescribing
- Nutritional support to improve lost weight

FLOWCHART 18.5: Pathophysiological basis of frailty.



Molecular and disease triggers
Impaired physiologic systems
Clinical frailty
• Oxidative stress
• Mitochondrial dysfunction
• DNA damage
• Cell senescence
Gene variation environment
Inflammatory diseases
Inflammation
Neuroendocrine dysregulation
↑ CRP
↑ IL-6
↓ IGF-1
↓ DHEA-S
↑ Cortisol
Anorexia
Sarcopenia, osteopenia
↓ Immune function
↓ Cognition
↑ Clotting
↓ Glucose metabolism
• Slowness
• Weakness
• Weight loss
• Low activity
• Fatigue

Q. Discuss failure to thrive, sarcopenia, and anorexia of aging.

Failure to Thrive

- It is a syndrome of weight loss, decreased appetite, poor nutrition, and inactivity, often accompanied by dehydration, depressive symptoms, impaired immune function, and low cholesterol.
- Affects following four main domains:
  1. Functional: BADL/IADL
  2. Malnutrition: Weight trend, body mass index (BMI), lymphocytes, and albumin
  3. Depression: ± Geriatric Depression Scale (GDS)
  4. Cognition: Confusion Assessment Method (CAM), standardized MMSE.

Management
- Interdisciplinary assessment and care planning
- Treat the cause

Sarcopenia

- Age-related loss of muscle mass
- Increases the risk for falls, fractures, dependency, use of hospital services, institutionalization, poor quality of life, and mortality
- Assessment: 5-item SARC-F (strength, assistance in walking, rise from a chair, climb stairs, and falls) score

Management
- Protein supplementation
- Resistance exercises

Anorexia of Aging

- The multifactorial decrease in appetite and/or food intake that occurs in late life.
- Specific geriatric syndrome that can lead to malnutrition if not appropriately diagnosed and treated.
- **Features:**
  - Body wasting (cachexia and sarcopenia)
  - Poor endurance
  - Reduced physical performance
  - Slow gait speed
  - Impaired mobility.
- Impacts survival independent of age, gender, and multimorbidity.
- Age-related reduction in smell and taste perception → alters food palatability and diet variety.
- Decreased gastrointestinal muscle tone and motility.
- Causes constipation and flatulence.
- **Risk factors:**
  - Functional impairment
  - Chronic medical conditions
  - Polypharmacy
  - Environmental factors—physical limitations causing mobility problems
  - Poor dentition/dentures
  - Depression—refusal to eat
  - Economic inequality
  - Social isolation—living alone/living in old age home.
- **Assessment**—the Simplified Nutritional Assessment Questionnaire (SNAQ) and Functional Assessment of Anorexia and Cachexia Therapy (FAACT) shortened 12-question version questionnaire.

Management
- Address reversible contributing factors/comorbidities
- Prescription review
- Improve food texture and palatability
- Protein supplementation—1–1.2 g/kg body weight

Multimorbidity and Polypharmacy

- **Multimorbidity:** The coexistence of ≥2 chronic conditions, where one is not necessarily more central than the others.
- **Polypharmacy:** Administration of more medications than clinically indicated, representing unnecessary drug use, i.e., ≥5 drugs during a 3-month period.
  - Appropriate polypharmacy: Prescribing for an individual for complex conditions or for multiple conditions in circumstances where medicines use has been optimized and where the medicines are prescribed according to best evidence.
  - Problematic polypharmacy: The prescribing of multiple (medicines) inappropriately, or where the intended benefit of the [medicines are] not realized.

GUIDELINES FOR DRUG THERAPY IN THE ELDERLY (BOX 18.13)

There are several reasons for the greater incidence of iatrogenic drug reactions in the elderly, the most important of which is the high number of medications that are taken by elders, especially those with multiple comorbidities.

Box 18.13: Guidelines for drug therapy in the elderly.

Recommended approach

- Use nonpharmacologic approaches whenever possible. Avoid *routine* use of "as needed" drugs for sleep, anxiety, pain.
- Choose the drug with the least toxic potential. Substitute less toxic alternatives whenever possible (antacid or sucralfate for an H_2-blocker or proton pump inhibitors, metamucil or kaopectate for imodium, scheduled acetaminophen regimen for pain management).
- Reduce the dosage. "Start low and go slow". Start with 25–50% of the standard dose of psychoactive drugs in the elderly. Titrate the drug slowly.
- Set realistic endpoints: Titrate to improvement, not elimination of symptoms. Keep the regimen simple. Regularly reassess the medication list. Re-evaluate long-time drug use because the patient is changing.
- Review over-the-counter medication use.
- **Deprescribing**—discontinuing a therapy prescribed for an indication that no longer exists, discontinuing therapy with side effects that may be contributing to frailty symptoms, substituting a therapy with a potentially safer agent.

Medication optimization is defined as 'a person-centered approach to safe and effective medicines use, to ensure people obtain the best possible outcomes from their medicines. Medicine optimization applies to people who may or may not take their medicines effectively. Shared decision-making is an essential part of evidence-based medicine, seeking to use the best available evidence to guide decisions about the care of the individual patient, taking into account of their needs, preferences and values'.

SOCIAL PROBLEMS/CHANGES IN OLDER ADULTS

Bereavement/Widowhood

Q. IM24.19 Enumerate and describe the social problems in the elderly including isolation, abuse, change in family structure and their impact on health.

Loss of a spouse is an important stage of transition in the life of an older adult. It often leaves the survivor confused, lonely and sad. The proportion of widows to widowers is much higher in most populations due to longer lifespans of women. This phase of widowhood may be much more damaging to women than to men due to various sociocultural factors. Widows usually end up becoming economically dependent on other family members. Widowhood still carries a social taboo among several communities in India,with widows being considered inauspicious and may be ostracized.

Impact on Health

- Affects both physical and mental health adversely.
- Bereavement period may be characterized by grief, difficulty in sleeping, lack of appetite and weight loss.
- May lead to depression.
- Increased morbidity, death and suicide rates are seen in recently widowed older adults.
- Physicians need to be sensitive to their emotional needs and vulnerability.

Loss of Social Status

Older adults once considered a wealth of wisdom in traditional societies end-up losing much of their social status in modern societies. Retirement, loss of occupation, loss of power and prestige and economic dependence all contribute to this loss of social status. Migration of the younger members of the family, changes in family structure, urbanization and advent of modern technology often leaves the older adult behind leading to loss of social status in them.

Change in Family Structure

With urbanization, family structures have changed from the earlier multigenerational joint families to nuclear families. Migration and smaller families result in older adults being left alone in their villages while younger adults live in cities/separately. Despite it being culturally unapproved in most societies in India, institutions such as oldage homes or assisted living centers and retirement communities may become increasingly necessary to fulfill needs of an increasing older adult population in India.

Impact on Health

- Often leads to loneliness and depression.
- Causes a lack of social support which leads to vulnerability (no help during emergencies, for medication use, for IADIs) and poor quality of life.
- Living alone becomes difficult with advancing age and when there is functional decline.

Ageism

It is a prejudice or discrimination against individuals or oneself-based on age. It is a process of stereotyping which often leads to neglect and elder abuse. It victimizes older adults. Doctors too may harbor negative attitudes about older adults. They may consider older adults to be annoying, ever complaining and consuming lots of their time. They may end-up dismissing key symptoms as due to age.

Impact on Health

- Ageism is associated with poorer mental and physical health and poor quality of life.
- It causes earlier death and slower recovery from disability among older adults.
- It is associated with unhealthy eating habits and increased risk of smoking and alcohol intake among older adults.

Combating Ageism

- Policy and law should be structured to protect older adults against discrimination.
- Educational activities can help to reduce prejudice and dispel misconceptions about older adults.
- Intergenerational activites can help to foster healthy attitudes towards older adults.

Isolation/Loneliness

Old age may be a time of isolation. Loneliness may result from social or psychological isolation. Loneliness may result due to any/all of the social changes discussed above. Loneliness may be subjective or objective in nature. It may reflect negative feelings. Migration, widowhood, changes in family structure may be common causes for isolation leading to loneliness. Decline in physical health, presence of geriatric giants, may result in loss of social activity. The environment may also lead to isolation of older adults. Environments which are filled with potential hazards such as the recent pandemic, presence of slippery floors, lack of grab bars, narrow doors, disability unfriendly public transport systems may all work to increase social isolation and aggravate loneliness among older adults.

Impact on Health

- Leads to depression, psychological distress and poor quality of life.
- Causes and worsens cognitive decline and dementia.
- Causes and worsens functional decline, promotes dependence and immobility.
- May lead to institutionalization.

Loneliness: It is the pain that we feel when our social connections do not meet our needs.

Social isolation: It is the state of having a small number of social contacts which may lead to loneliness.

Elder Abuse

- More than a million people world over aged 65 or older have been injured, exploited, or otherwise mistreated by someone on whom they depended for care or protection. Neglect is the most common form of abuse followed by financial and emotional abuse.
- Elder abuse can be suspected when the patient exhibits behavioral changes in the presence of the caregiver, delays between occurrence of injuries and sought treatment, inconsistencies between an observed injury and associated explanation, lack of appropriate clothing or hygiene, and not filling prescriptions.
- Many elders with cognitive impairment become targets of financial abuse.
- Abuse and self-neglect has increased risk of mortality.
- **Who are the abusers?**
  - Domestic elder abuse (caregivers/distant relatives)
  - Institutional elder abuse
  - Self-abuse/neglect

- **Reasons for abuse**
  - Caregiver stress/burnout
  - Impairment of dependent elder (i.e., dementia)
  - Transgenerational "cycle of violence"
  - Material or other gain
- About half of the elderly population in the country face some form of abuse, more in case of women than men.

Major Forms of Abuse

- **Physical and sexual abuse:** Any act of violence or rough treatment, whether or not actual physical injury results, e.g., slapping, punching, kicking, pinching, burning, restraints.
- **Emotional and psychological abuse:** Any act that diminishes dignity and self-worth, e.g., confinement, isolation, verbal assault, humiliation, and infantilization.
- **Financial abuse and material exploitation:** Any improper conduct that results in monetary or personal loss for the older adult.
- **Abandonment and neglect**
  - **Active neglect:** Intentional (deliberate) withholding of basic necessities and/or care for physical or mental health.
  - **Passive neglect:** Not providing basic necessities and care. There is no conscious attempt to inflict distress.
- **Medical abuse:** Any medical procedure or treatment done without the permission of the older person or their Power of Attorney or substitute decision maker.

Box 18.14: Indicators of abuse.

- Unexplained physical injury
- Unexplained malnutrition/decubitus ulcers
- Unkempt appearance
- Failure of a medical condition to improve or the continued presence of pain
- Fear of certain family members, friends, or caregivers
- The older person is largely ignored or treated passively by caregivers or others
- Caregivers who are entirely ignorant of the medical problems or treatments for the older person they are directly caring for.

Indicators of abuse are listed in **Box 18.14**.

Q. IM24.20 Enumerate and describe social interventions in the care of elderly including domiciliary discussion services, rehabilitation facilities, oldage homes and state interventions.

The social interventions for better quality of life in old age are:

- **Social networking and communication:** Older adults need to actively foster and maintain social relationships such as with family, neighbors, community and colleagues. A wider social network helps to protect from isolation and the adverse effects of loneliness.
- **Voluntary work:** Non-Governmental Organizations (NGOs), and social work professionals can help to develop social networks for older adults within the community.
- **Educational activities, learning new technologies:** Higher literacy levels and greater cognitive skills help to reduce health risks and risks of disability and death in later life. Older adults with higher levels of education retain their ability to remain engaged and productive through their later years. Training of older adults in newer technologies and in methods of communication through social media networks helps to create inclusivity and intergenerational bonding which promotes positivity and better attitudes towards older adults.
- **Protection against violence and abuse:** Older people are increasingly at higher risk of threats such as theft, assault, financial fraud, but the most common form of violence against older adults is from elder abuse, which is often committed by members of their family or by caregivers who are known to the victims.
  - Strategies to combat abuse are:
    - Caregiver interventions to relieve the burden of caregiving
    - Money management programmes for protection of older adults who are at a risk of financial exploitation
    - Helplines and emergency shelters
    - A multidisciplinary approach is needed to solve the menace of violence and abuse. It should include systems of criminal justice, health care, mental health care, adults protective services and long-term care. The solutions are difficult to achieve currently in India.
- **Policy and Laws:**
  - The National Policy on Older Persons was launched in 1999. It ensures support for financial and food security, health care, shelter and other needs of older persons, equitable share in development, protection against abuse and exploitation, and availability of services to improve the quality of their lives.

- Among the several legal rights available to senior citizens in India, mention is to be made of the **Maintenance and Welfare of Parents and Senior Citizens Act, 2007**. This act allows parents and grandparents who are unable to maintain themselves from their own income to demand maintenance from their children. Maintenance includes provision for food, clothing, residence, medical attendance, and treatment. The maximum amount which may be ordered for maintenance of a senior citizen by the Tribunal shall be such as prescribed by the state government which shall not exceed ₹ 10,000/- per month. Noncompliance of the this order may result in fine or imprisonment for upto a month or until the dues are paid.

There are several statewise benefits and central government schemes providing various types of concessions and benefits to senior citizens. Various senior citizen welfare organizations are also present that provide various services to senior citizens in India.

There are over 1200 oldage homes in India, which offer various services for long-term care.

ETHICS IN GERIATRICS

Respect for Autonomy

Q. IM24.21 Enumerate and Describe Ethical Issues in the Care of the Elderly.

One of the key ethical issues which come to the fore in managing the care of older adults is *autonomy*. Older adults often lack decision-making capacity and hence need to depend on others for key decisions. Older adults should be allowed to have the right to self-determination regarding their health and care options. Family or caregivers may often lose sight of the autonomy of older adults in the process of care which may result in abuse or neglect or even overtreatment.

Paternalism

It is the process of taking decisions for the benefit of another person. Older adults are often subject to paternalism. It is to be noted that when the decisions do not benefit the older adults or/are against the decisions of the older adults, the same decisions or acts can be construed to be coercive and could be in direct violation of the patient's autonomy and right to self-determination.

Dignity

Another ethical issue that takes center stage in the context of geriatric medicine is ***dignity.***

Respecting and preserving the dignity of an older adults holds great value. By respecting their autonomy and their wishes during their care we can help in preserving their dignity. Older adults with functional impairment often need help with activities of daily living. Assistance during ADLs and other tasks for grooming and care of tubes and medical devices may often cause older adults to feel a sense of loss of dignity. The utmost care and sensitivity by healthcare professionals is essential to preserve their dignity during care.

Q. IM24.16 Describe and discuss the principles of physical and social rehabilitation, functional assessment, role of physiotherapy and occupational therapy in the management of disability in the elderly.

Rehabilitation has emerged in recent years as medical speciality. Physical/medical rehabilitation refers to a process of restoration of physical function. It includes restoration of motor power, hearing loss, speech, swallowing, etc. It aids in improvement of activities of daily livings (ADLs).

Social rehabilitation means restoration of family and social relationships. Vocational rehabilitation refers to restoration of one's capacity to earn a livelihood. Psychosocial rehabilitation helps to restore personal dignity and confidence of a person.

Physical rehabilitation can be done through exercises, use of splints, prosthetic devices, heat, cold or through training of gait and other educational activities.

Rehabilitation is provided by various rehabilitation specialists such as physical therapists, occupational therapists, speech language pathologists, psychologists, physiatrists, etc.

Occupational therapists have the following role:

- To assess the functions and functional deficits
- To assess ADL (activity of daily living) and ADL deficit
- To use activities for functional restoration and restoration of ADLs
- To make and use self-help devices.

Q. IM24.15, 24.17 Discuss the etiopathogenesis, clinical presentation, identification, functional changes, acute care, stabilization, management and rehabilitation of visual and hearing loss in the elderly.

Visual Loss in Older Adults

Common causes of visual loss in older adults include:

- Cataract
- Diabetic/hypertensive retinopathy
- Presbyopia
- Hemianopia

Speech and Hearing Loss in Older Adults

Common causes:

- Presbycusis
- Aphasia due to stroke
- Cerumen accumulation (wax)

Presbycusis refers to age-related hearing loss, occurring mostly beyond the age of 60 years. The hearing loss is progressive and bilaterally symmetrical. It causes impairment in ability to understand high frequency components of speech. The cause is multifactorial and can be due to genetic, ototoxic, hormonal causes or due to noise exposure. The patients often have a difficulty in discriminating speech in the presence of background noise. It is a sensorineural type of hearing loss. ***Diagnosis*** is made by pure-tone audiometry. There is no cure for presbycusis. Some older adults benefit from use of hearing aids.

CHAPTER 19

Dermatology, Venereology and Leprosy

INTRODUCTION

Description of Primary Skin Lesions (Fig. 19.1)

Q. Define primary skin lesions and give examples.

 Macule	*Description:* A circumscribed flat, colored lesion, <2 cm in diameter, with sharp borders, not raised above the surface of the surrounding skin. *Examples:* Freckle, rashes of rickettsial infections, rubella	 Vesicle	*Description:* A small, fluid-filled lesion, <0.5 cm in diameter, raised above the plane of surrounding skin. *Examples:* Herpes infections, acute allergic contact dermatitis, dermatitis herpetiformis
 Patch	*Description:* A large (>2 cm) flat lesion with a color different from that of surrounding skin. *Example:* Vitiligo	 Bulla	*Description:* A fluid-filled, raised, often translucent lesion >0.5 cm in diameter. *Examples:* Burns, pemphigus vulgaris, bullous pemphigoid
 Papule	*Description:* A small, solid, <0.5 cm in diameter, without fluid, lesion raised above the surface of the surrounding skin with sharp borders. *Examples:* Nevi, warts, lichen planus, seborrheic and actinic keratosis	 Wheal	*Description:* An evanescent elevated lesion with erythema and edema frequently with central pallor. *Example:* Urticaria
 Nodule, tumor	*Description* *Nodule:* A palpable, large (0.5–5.0 cm), firm/solid lesion with distinct border raised above the surface of the surrounding skin. *Tumor:* A solid, raised growth >5 cm in diameter. *Examples:* Cysts, lipomas, fibromas	 Pustule	*Description:* A vesicle filled with pus (leukocytes). *Example:* Folliculitis
 Plaque	*Description:* A large (>1 cm), flat-topped, raised area of skin. *Examples:* Psoriasis, granuloma annulare	 Telangiectasia	*Description:* A visible dilatation of small cutaneous blood vessels. *Example:* Hereditary hemorrhagic telangiectasia

FIG. 19.1: Schematic representation of common primary skin lesions.

Description of Secondary Skin Lesions (Fig. 19.2)

Q. Define secondary skin lesions and give examples.

	*Description:* Partial loss of epidermis, which will heal without scaring.		*Description:* Full thickness loss of epidermis and some dermis, which will heal with scaring.
	*Description:* Depression of the surface due to thinning of the epidermis or dermis.		*Description:* Linear split in the epidermis or dermis at an orifice (angle of the mouth or anus).
	*Description:* Dry/flaky surface due to abnormal stratum corneum with accumulation of or increased shedding of keratinocytes. *Example:* Psoriasis		*Description:* Thickening of the epidermis with exaggerated skin markings. *Example:* Lichen planus.

FIG. 19.2: Schematic representation of common secondary skin lesions.

PAPULOSQUAMOUS DISORDERS

Psoriasis

Q. DR3.1, 3.2, 3.3 Define psoriasis. Mention the factors precipitating the disease and its pathogenesis. Describe the typical presentation and clinical features of psoriatic lesions. Briefly define grattage test. Discuss the types and describe the various modalities of treatment of psoriasis including topical, systemic, drugs, and phototherapy.

It is a noninfectious, chronic papulosquamous, T-cell-mediated inflammatory skin disorder and is one of the most common skin diseases. It usually follows a relapsing and remitting course.

- **Gender:** It equally affects males and females.
- **Age:** It occurs in two peaks of age.

Two basic types of psoriasis have been distinguished, depending on the age of onset:

1. Type I (juvenile), considerably more common, characterized by autosomal dominant inheritance, with onset usually occurring between 20 and 40 years of age. The majority of patients with type I psoriasis carry the HLA- Cw6 antigen. The course of the disease is more severe, with high resistance to treatment.
2. Type II (adult) usually affects the older population, between 50 and 60 years of age. HLA-Cw6 is uncommon in this group of patients, while the disease tends to have a milder course.

Etiology

The exact etiology of psoriasis is not known.

- **Genetic factors:** The genetic component is complex and polygenic. There is a clear genetic predisposition (with a positive family history in >50% of patients) in association with certain environmental triggers. Nine susceptibility genes have been identified *(PSORS1* to *PSORS9),* most important being *PSORS1* (on chromosome 6p21.3).
- **Environmental factors:** Several environmental triggers produce psoriasis in a genetically predisposed individual. These include infections, stress, physical injury, trauma, smoking, alcohol, and drugs.

Pathogenesis

- Psoriasis results from **interactions of genetic and environmental factors**. There is a shortened cell cycle time for keratinocytes (36 hours compared with 311 hours in normal skin) and a decreased turnover time of the epidermis (4 days from basal cell layer to stratum corneum, compared with 27 days in normal skin).
- Available evidence suggests that cells in genetically susceptible individuals, triggering factors activate the antigen-presenting cells (dendritic/Langerhans), which in turn activate $CD4^+$ TH1 and TH17 cells via interleukin (IL)-12 and IL-23, respectively and these T cells enter the skin and accumulate in the epidermis. These T cells secrete mediators [tumor necrosis factor (TNF)-α and interferon-γ by TH1; IL-17A, 17F and 22 by TH17], which activate keratinocytes to produce antimicrobial peptides (e.g., β-defensins), cytokines (e.g., TNF-α, IL-1β, and IL-6) and chemokines.

Pathology

- Increased epidermal cell proliferation (hyperproliferation of keratinocytes): Proliferation of the subepidermal vasculature leads to dilated, tortuous blood vessels within the dermal papillae surrounded by a mixed neutrophilic and lymphohistiocytic perivascular infiltrate.
- Dense inflammatory cell infiltrates. Polymorphonuclear abscesses may be seen within mildly spongiotic foci of the superficial epidermis **(spongiform pustules)** and within the parakeratotic stratum corneum **(Munro's microabscesses)**.

Clinical Features

- Psoriasis can involve the **skin, scalp, and nails** and can present with different clinical patterns.
- Clinically, skin lesions are characterized by well-defined pink-red, sharply demarcated macules, papules, or rounded plaques that are usually covered by silvery scales with a whitish halo around lesions **(Woronoff's sign)**.
- It predominantly affects **extensor surfaces** and scalp, and has a chronic fluctuating course. *There is increased association of psoriasis with HIV infection.*
- **Grattage test:** Scales in a psoriatic plaque can be accentuated by grating with a glass slide.
- **Auspitz sign:** Three steps—
  - *Step 1*: Gently scrape lesion with a glass slide—this accentuates the silvery scales (Grattage test positive). Scrape off all the scales.
  - *Step 2*: Continue to scrape the lesion—a glistening white adherent membrane (**Burkley's membrane**) appears.
  - *Step 3*: On removing the membrane, punctate bleeding points become visible—positive Auspitz sign **(Fig. 19.3)**.
- If the surface of psoriatic plaque is scraped with a blunt scalpel, squamae fall off as layers of white lamellae that exhibit coherence after removal, much like candle wax. This desquamation is sometimes referred to as **candle-grease sign** /**"wax spot phenomenon**." It is a sign of parakeratotic hyperkeratosis.
- If psoriatic plaque is scraped further, a wet layer adhered to the lesion can be revealed. This is the last layer of the dermal papillae of the epidermis, and it is a pathognomonic sign of psoriasis, known as "**last membrane phenomenon."**

Types of Psoriasis

See **Box 19.1**.

Box 19.1: Types of psoriasis.

- Plaque psoriasis (psoriasis vulgaris), chronic plaque psoriasis
- Guttate psoriasis (small rain drop-like psoriatic lesions)
- Inverse psoriasis (flexural psoriasis)
- Localized pustular psoriasis
- Generalized pustular psoriasis
- Palmoplantar psoriasis
- Erythrodermic psoriasis
- Von Zumbusch psoriasis (pustular + erythroderma)

Plaque Psoriasis (Psoriasis Vulgaris), Chronic Plaque Psoriasis

- It is most common form and accounts for 90% of cases.
- Lesions (**Figs. 19.4A and B**):
  - Symmetrically distributed plaques involving the scalp, extensor surfaces of the elbows, knees, gluteal cleft, lower back, ears and back. Plaques 1–10 cm in diameter with raised, well-defined margins

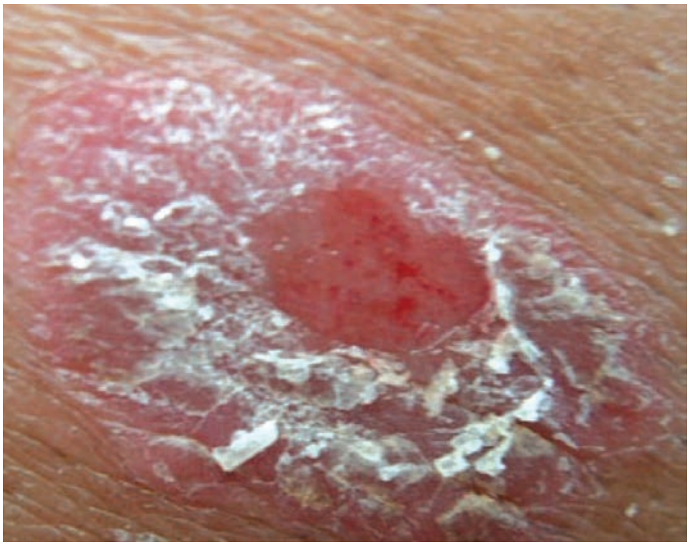


FIG. 19.3: Auspitz sign, multiple pinpoint bleeding observed on scraping the scales in psoriasis.

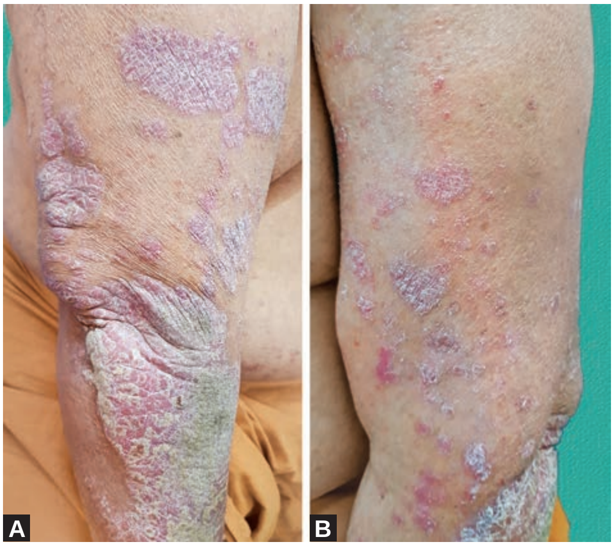

FIGS. 19.4A AND B: Skin lesion of psoriasis.

  - Thick silvery scales frequently present (although bathing may remove scale)
  - Classically asymptomatic, although some patients report pruritus, irritation, or pain
  - Pitting of nail plates and involvement of intertriginous areas (umbilicus and intergluteal cleft) may occur.
  - Psoriatic lesions can be induced in susceptible individuals by minor local injury/trauma, a process known as the **Koebner phenomenon** (**Fig. 19.5**).
- **Exacerbating factors**: Drugs (lithium, β-blockers, chloroquine, NSAIDs, ACE inhibitors, and terbinafine), infections (bacterial and viral), and ethanol abuse.

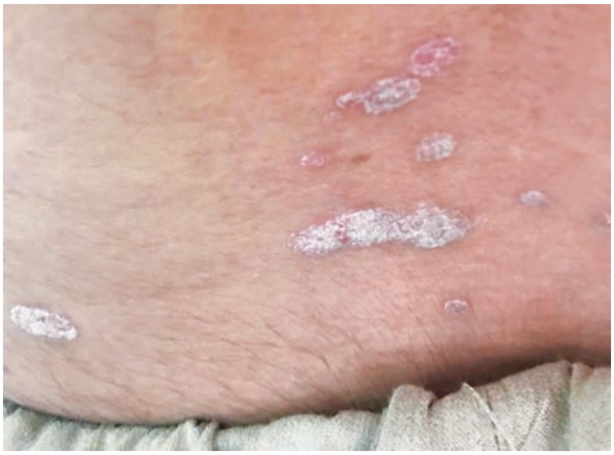

FIG. 19.5: Koebner phenomenon in psoriasis.

Associated Features of Psoriasis

- **Nails (Fig. 19.6):** Involvement is common and may be observed up to 50% of patients with psoriasis. These include—(a) "thimble pitting" of the nail plate, (b) distal separation of the nail plate from the nail bed (onycholysis), (c) yellow–brown discoloration underneath the nail plate ("oil drop" sign), (d) subungual hyperkeratosis, and (e) thickening of the nail (onychodystrophy).
- **For diagnosis of nail involvement:** More than six nails should be involved with each nail having >20 pits.
- **Psoriatic arthropathy:** It may be seen in 5–10% of psoriatic patients. It usually develops several years after appearance of skin lesions and most of these will have nail changes. It is a form of chronic seronegative spondyloarthropathy (discussed in Chapter 8).
- **Others:** It may be associated with comorbidities such as ulcerative colitis, Crohn's disease, coronary artery disease, metabolic syndrome, and lymphoma.

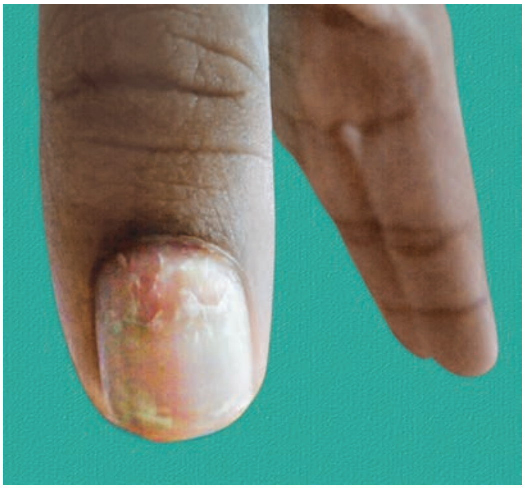

FIG. 19.6: Nail changes in psoriasis.

Investigations and Diagnosis

In most cases, the diagnosis can be made based on the history and physical examination alone. Biopsy is seldom necessary.

Management of psoriasis

Treatment depends on the type, location, and extent of disease.

General management

- Education, explanation, reassurance, and instructions are important.
- Instructed to avoid excess drying or irritation of skin and to maintain adequate hydration of skin

Treatment can be divided into four broad categories namely—(1) topical agents, (2) ultraviolet (UV) therapies, (3) systemic agents, and (4) biological therapies.

Treatment of psoriasis vulgaris: A three step approach.

Step 1: Topical treatments

- **Emollients/moisturizers:** Petroleum jelly and thick creams, especially effective when applied after hydrating bath or shower
- **Topical corticosteroids:** These are mainstay for treatment. Moderate to high potency ointments (e.g., betamethasone 0.5%) ± occlusion by tape or plastic wrap are recommended for thick plaques on extensor surfaces, whereas low-potency ointments (e.g., 0.05% fluocinonide) are usually sufficient for face and intertriginous areas.
- **Coal tar:** Usually used in conjunction with steroids, although can be used alone
- **Calcipotriene and Calcitriol:** Vitamin D_3 analog that affects growth and differentiation of keratinocytes
- **Tazarotene:** Topical retinoid (vitamin A derivative)
- **Topical calcineurin inhibitors**: Topical **tacrolimus and pimecrolimus**
- **Salicylic acid**: Keratolytic that softens and removes scale from plaques, allowing topical meds to penetrate
- Topical anthralin

Q. Discuss PUVA (psoralen and ultraviolet A) therapy in psoriasis.

Step 2: Phototherapy: *Effect likely through immunomodulatory properties*

- **Sunlight**: Careful sun exposure may improve psoriasis, but sunburn may exacerbate it.
- **UVB (295–320 nm) radiation:** Erythema inducing doses (3–5×/week until remission) are used for moderate to extensive disease, alone or in combination with topical tar.
- **UVB narrow band (311 nm)**: It has been shown to be more effective than the broader band in some studies, inducing more apoptosis of T-cells.
- **Psoralen and ultraviolet A:** Photochemotherapy with oral psoralen (8-methoxypsoralen) followed by exposure to UVA (320–400 nm) radiation is used for moderate-to-severe disease when UVB fails. It is effective (75% of patients note marked improvement), but increases risk for cataract, pigmentation, premature skin aging, and skin cancer. Psoralens are natural photosensitizers found in many plants. Psoralen molecules intercalate between the two strands of DNA and on excitation with ultraviolet A (UVA), photons cross-link the DNA strands. It is thus a pro-drug, which after oral administration is distributed throughout the body, but only activated in skin that is exposed to UVA. Other uses of PUVA include vitiligo, mycosis fungoides, atopic dermatitis, and senile pruritus. Risk of skin cancer and folate deficiency is associated with PUVA therapy.
- **High-energy 308-nm excimer laser:** It treats only involved skin and allows higher doses to be delivered to the plaques, compared with traditional phototherapy.
- Two regimens used commonly are:
  1. *Goeckerman regimen:* UVB + coal tar
  2. *Ingram regimen:* Coal tar + UVB + dithranol

Step 3: Systemic therapy

- **Methotrexate:** It is effective in severe psoriasis, psoriatic arthritis, and psoriatic nail disease.
- **Acitretin:** Vitamin A analog used for treatment of severe psoriasis, especially pustular and erythrodermic variants. It is a teratogen and pregnancy is contraindicated for 3 years after discontinuing the drug. It may be used in combination with UVB or PUVA.
- **Cyclosporine:** T-cell suppressor indicated for severe psoriasis not responsive to other agents
- **Apremilast**, a phosphodiesterase 4 inhibitor, is indicated for the treatment of moderate-to-severe plaque psoriasis.

Biologics, immunomodulatory drugs

- **Etanercept**: Recombinant TNF-alpha inhibitor, approved for treatment of psoriatic arthritis and for adults with moderate-to-severe plaque psoriasis
- **Alefacept:** Recombinant protein that binds to CD2 receptor on T-lymphocytes
- **Efalizumab**: It is monoclonal antibody to CD11a. It is approved for moderate-to-severe plaque psoriasis
- **Infliximab:** TNF-alpha inhibitor

- Human interleukin-12/23 monoclonal antibody:
  - **Ustekinumab,** a fully human monoclonal antibody against the p40 subunit of IL-12 and IL-23, is effective.
  - **Guselkumab** is a human immunoglobulin G1 (IgG1) lambda monoclonal antibody that binds to the p19 subunit of IL-23.
- *Monoclonal antibody against the p40 molecule shared by IL-12 and IL-23*: For example, **briakinumab** is effective in moderate and severe psoriasis.
- **Risankizumab** is a humanized monoclonal antibody directed against the p19 subunit of IL-23 and IL-39.
- **Brodalumab** (an anti-IL-17 receptor antibody) and ixekizumab (an anti-IL-17 monoclonal antibody) can also be effective in psoriasis.

Newer treatment options:
- **Climatotherapy** (bathing in sea water in combination with sun exposure)
- **Balneophototherapy** (salt water baths with artificial UV exposure)

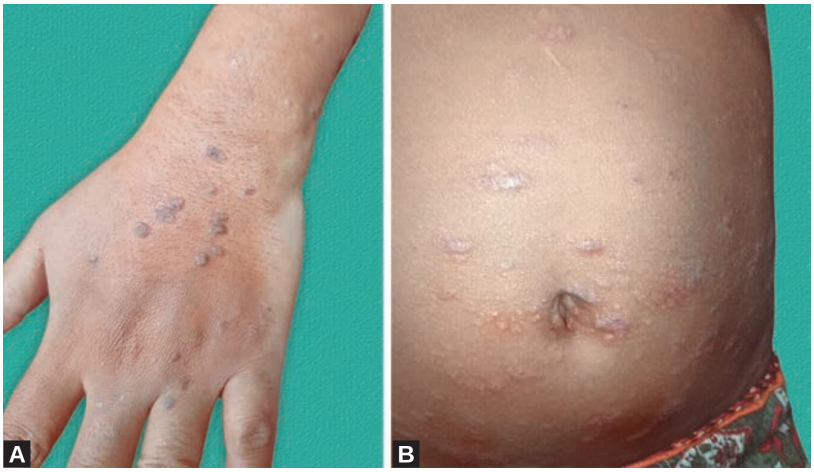
Lichen Planus

Q. DR4.1, 4.2 **Define lichen planus. Describe the clinical features and treatment modalities for lichen planus.**

Lichen planus is a pruritic inflammatory dermatosis that is commonly associated with mucosal involvement. It may affect the skin (cutaneous lichen planus), oral cavity (oral lichen planus), genitalia (penile or vulvar lichen planus), scalp (lichen planopilaris), nails, or esophagus.

Etiology

Autoimmune: An autoimmune mechanism is suspected because of its association with hepatitis C, inflammatory bowel disease, primary biliary cirrhosis, autoimmune hepatitis, hepatitis B, alopecia areata, myasthenia gravis, and thymoma. There are similarities with graft-versus-host disease (GVHD). Drugs, such as thiazides, INH, allopurinol, angiotensin-converting enzyme (ACE) inhibitors, and antimalarials, can produce lichenoid eruptions.



FIGS. 19.7A AND B: Skin lesions in lichen planus.

Clinical Features

Age and gender: Lichen planus affects women more than men (at a ratio of 3:2) and occurs most often in middle-aged adults.

Characteristics of lesion

- **Skin lesions (Figs. 19.7A and B):**
  - The typical rash of lichen planus is well described by the "5 P's": Well-defined **pruritic, planar, purple, polygonal papules, or plaques.**
  - **Sites involved:** Flexor surfaces especially wrists, flanks, medial thighs, shins of tibia, glans penis, nails, scalp, and oral mucosa.
  - There may be a characteristic fine lacy white pattern (network) on the surface of lesions **(Wickham's striae).**
  - **Koebner's phenomenon** is observed.
  - After lesions subside, post-lichen hyperpigmentation occurs.
- **Mucous membrane:** Involvement is common (30–70%) and prominent symptom is of severe pain rather than itch. The mouth is the most commonly affected. It can also affect genital and other mucosal surfaces.
- **Nail involvement:** Occurs in about 10% and causes a thinning of the nail with longitudinal ridges and may progress to complete loss of the nail plate **(pterygium formation)** (**Fig. 19.8**).
- **Scalp involvement:** Lichen planopilaris is the specific name given to lichen planus on the scalp that may cause permanent, scarring alopecia.

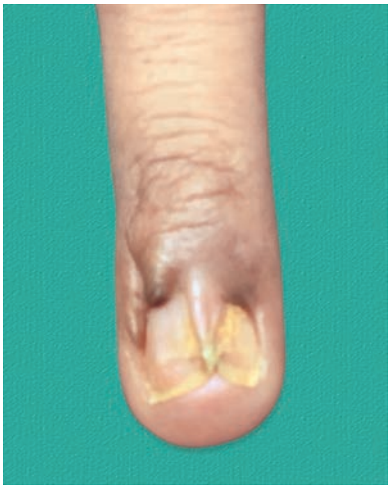


FIG. 19.8: Nail changes (pterygium formation) in lichen planus.

Diagnosis

Histological changes: Characteristic histological changes include—(1) hyperkeratosis with thickening of the granular cell layer, (2) basal cell degeneration, and (3) dense, band-like T-lymphocyte infiltrate at the dermal–epidermal junction, with affinity for the epidermis (epidermotropism). The dermoepidermal junction becomes ragged and appears "saw-toothed". The basal layer shows liquefactive degeneration with colloid (apoptotic) bodies, **Colloid or Civatte bodies** in the upper dermis.

Prognosis

It is usually self-limiting and often clears by 18 months but can recur at intervals.

Complications of Lichen Planus (Box 19.2)

Box 19.2: Complications of lichen planus (LP).

- Squamous cell carcinoma in oral ulcerative lesions
- Cicatricial alopecia in scalp LP
- Postinflammatory hyperpigmentation

Management

- Treatment is symptomatic.
- *Topical corticosteroids*: Potent local corticosteroids (e.g., 0.05% clobetasol propionate, 0.1% triamcinolone ointment, twice daily for 2–4 weeks) are helpful in patients with limited disease. Oral lesions may require high-potency steroids given as an ointment, gel, or mouthwash. Topical 0.1% tacrolimus ointment or pimecrolimus may be very useful for painful oral disease unresponsive to steroids.
- *Oral therapy*: Short courses of systemic corticosteroids (oral prednisolone 30 mg daily for 2–4 weeks) are sometimes required for extensive disease.
- Widespread lichen planus may require UVB, PUVA, or UVA1 and in resistant cases, retinoids or immunosuppressants such as azathioprine and ciclosporin may be helpful.
- Hydroxychloroquine and dapsone have also been tried.

Acanthosis Nigricans

Q. Write short note on acanthosis nigricans (AN).

It is a skin lesion marked by thickened, verrucous (warty) hyperpigmentation of the skin with a velvety texture (**Fig. 19.9**) predominantly of the flexural areas (axillae, skin folds of the neck, groin, and anogenital regions) including the lips.

- In 80% of cases, it is associated with benign conditions [most commonly with obesity, **insulin resistance**, and diabetes, and drugs such as nicotinic acid, fusidic acid, stilbestrol, oral contraceptive pills (OCPs)] and develops gradually, usually during childhood or puberty. They are associated with very high levels of insulin owing to insulin resistance. Obesity-associated AN is sometimes termed "pseudoacanthosis nigricans".
- In the remaining cases, it arises in association with underlying cancers (most commonly *gastrointestinal adenocarcinomas),* usually in middle-aged and older individuals. In this setting, it occurs as a paraneoplastic phenomenon caused by growth factors released from tumors. Other tumors producing this are Wilm's tumor and malignant tumors of bronchus, pancreas, ovary, bile duct, gallbladder, breast, and thyroid.

Associated thickening of palms with accentuated dermatoglyphics is called **Tripe palms. Acrochordons (skin tags) may be present.**

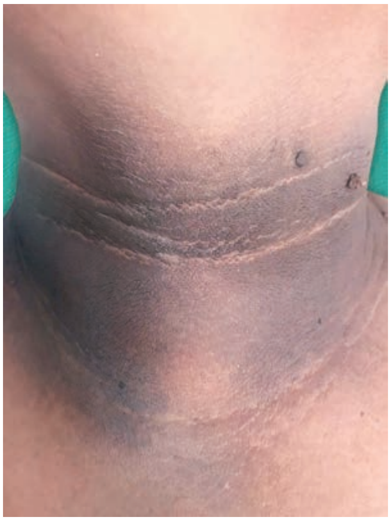

FIG. 19.9: Skin lesions of acanthosis nigricans.

Treatment

- Treat any underlying disease/malignancy.
- Weight loss is advised in the obese.
- Topical or oral retinoids (0.5 mg/kg per day) may be helpful.

Few may benefit from metformin, oral isotretinoin, topical retinoic acid, topical salicylic acid, and oral fish oil.

Eczema

Q. DR12.1, 12.2 ,12.3 Describe the etiopathogenesis of eczema. Classify and grade eczema. How to differentiate it from lichenification?

Q. DR12.4 Enumerate the drugs used in the treatment of eczema. Briefly mention there side effects.

Eczema is catarrhal inflammation of a sensitive skin, synonymous with the term dermatitis. Eczema is not a specific disease entity and may develop as a final common response of the skin to several causes. These causes may be either exogenous or endogenous in origin. It presents with spectrum of clinical presentation from acute through to chronic. Acute type is histologically characterized by spongiosis (intercellular edema of the epidermis) and intraepidermal vesiculation (producing multilocular blisters). Chronic eczema shows more epidermal thickening (acanthosis).

Classification of Eczema

See **Table 19.1**.

TABLE 19.1: Classification of eczema.

Endogenous	***Exogenous***
➢ Atopic eczema ➢ Discoid eczema (nummular eczema) ➢ Seborrheic eczema ➢ Hand eczema ➢ Venous ("gravitational")/asteatotic eczema ➢ Pityriasis alba, pompholyx	➢ Contact eczema: – Irritant – Allergic ➢ Photosensitive eczema ➢ Lichen simplex/ nodular prurigo ➢ Infective dermatitis

Atopic Dermatitis

Q. Write short essay/answer on atopic dermatitis.

Atopic dermatitis (AD) is an endogenous type of eczema that develops in individuals who are "atopic" and is the cutaneous expression of the atopic state. Atopic state is characterized by a family history of asthma, allergic rhinitis, or eczema.

Box 19.3: Clinical features of atopic dermatitis.

- Family history of atopy (asthma, allergic rhinitis, food allergies, or eczema)
- Itching and scratching
- Lichenification of skin (in adults)
- Dry skin (xeroderma)
- Course:
  - Characterized by exacerbations and remissions
  - Lasts for >6 weeks

Etiology

The exact pathophysiology is partially defined in atopic dermatitis.

- **Genetic factors:** Atopic eczema is a genetically complex familial disease and often associated with positive family history of atopic disease (90% concordance in monozygotic twins but only 20% in dizygotic twins).
- **Environmental allergens:** Atopy is characterized by generalized and prolonged hypersensitivity to common environmental antigens (e.g., pollen, food, animal hair, and house dust mite). Atopic individuals develop one or more of a group of diseases such as asthma, hay fever, food and other allergies, and atopic eczema.
- **Epidermal barrier impairment:** It is a major and perhaps primary factor in atopic eczema. It was observed in Caucasian individuals that loss of function mutations in the epidermal barrier protein filaggrin can predispose to atopic eczema. *Filaggrin* is coded by *FLG* gene on chromosome 1q21.

Exacerbating factors: Factors that can exacerbate eczema include—

- **Infection:** Infection in the skin or systemic infection can exacerbate atopic eczema. Paradoxically, lack of infection (in infancy) may allow eczema to develop **("hygiene hypothesis").**
- **Irritants:** Such as strong detergents, chemicals, and woolen clothes
- **Severe anxiety or stress** in some individuals
- **Others:** Cat and dog fur, food allergens, dairy products, or eggs

Clinical features (Box 19.3)

Age: Atopic eczema is most commonly seen among young children. About 50% present within the 1st year of life, and 80% present by 5 years of age.

Character of lesion (Fig. 19.10)

- Primary lesions include erythematous macules, papules, and vesicles, which can coalesce to form patches and plaques. **The most common presentation** is extremely **itchy erythematous scaly patches** accompanied by scratching.
- The symptom of itch is so central in the pathogenesis that atopic dermatitis is described as **"the itch that rashes and not the rash that itches".**
- It may also present as widespread cutaneous dryness (roughness).
- **Acute lesions** can produce small vesicles. In severe cases, secondary lesions from infection or excoriation (due to scratching) may be marked by weeping and crusting.
- **In chronic lesions,** repeated rubbing produces lichenification.

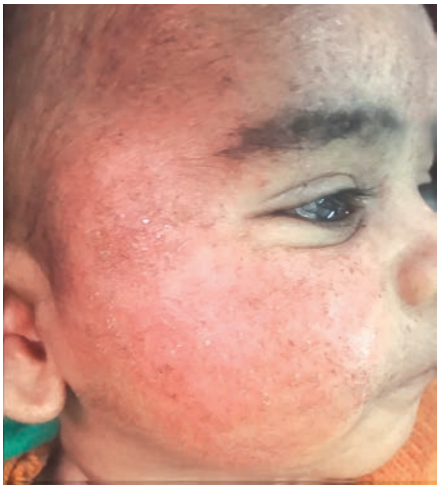

FIG. 19.10: Skin lesions of atopic dermatitis.

Distribution of lesion: Varies with age—

- Lesions are usually found in the periorbital area and the **flexor areas such as in front of the elbows and ankles,** behind the knees (popliteal fossae) and around the neck.
- In **infants, eczema** usually starts on the **face** before spreading to the body.

Cutaneous and vascular stigmata of atopic dermatitis (Table 19.2)

TABLE 19.2: Cutaneous and vascular stigmata of atopic dermatitis.

Cutaneous stigmata	*Vascular stigmata*
➢ **Dennie–Morgan** infraorbital fold ➢ Pityriasis alba ➢ Keratosis pilaris ➢ **Hertoghe's sign—**thinning of the lateral eyebrows	➢ **Headlight sign—**perinasal and periorbital pallor ➢ **White dermographism** (**Fig. 19.11**)—blanching of the skin at the site of stroking with a blunt instrument— causes edema and obscures color of underlying vessels

Diagnosis: It is made based on—(1) morphologic features, (2) the distribution of the lesions, and (3) a family and personal history of atopy. About 80% of patients may have high serum IgE levels or high specific IgE levels to certain ingested or inhaled antigens and a blood eosinophilia. Hanifin and Rajka criteria are used for diagnosis.

Complications of atopic eczema (Box 19.4)

Box 19.4: Complications of atopic eczema.

Secondary infection

- *Bacterial*: *Staphylococcus aureus* is most common
- *Viral*: For example, viral warts and *Molluscum contagiosum*, especially if treated with topical corticosteroids. Herpes simplex virus (HSV) can cause severe widespread eruption (eczema herpeticum).

Increased susceptibility to irritants due to defective barrier function

Increased susceptibility to allergy:

Food allergy mainly in infants, e.g., egg, cow's milk, protein, fish, and wheat may cause an urticarial eruption.

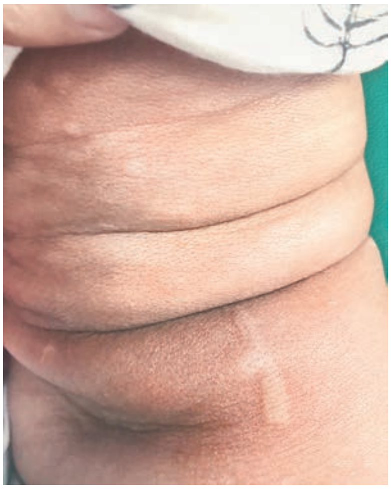

FIG. 19.11: Dermographism seen in urticaria and atopic dermatitis.

Management

General measures

Atopic eczema—

- Education, explanation, and reassurance
- Avoidance of contact with skin irritants (especially soaps or furry animals), heat, and dryness. Advised to wear cotton clothes
- **Emollients for moisturizing:** Emollients are used to moisturize, lubricate, protect, and soften skin
- **Topical anti-inflammatory agents:**
  - **Topical corticosteroid ointments:** They should be used judiciously. Depending on the potency, topical corticosteroids can be divided into five groups (**Table 19.3**). Mid-potency topical glucocorticosteroids are used in most treatment regimens.
  - **Topical immunomodulators:** These include two macrolide immunosuppressant namely tacrolimus ointment (0.1% for 3–4 weeks), and pimecrolimus cream (1% for 3–4 weeks).

The "triple" combination of topical steroid, emollients, and bath oil and soap substitute (e.g., aqueous cream) is usually helpful.

- **Adjunct therapies:**
  - **Oral antihistamines:** Control of pruritus is most often achieved by use of antihistamines. These include fexofenadine, 180 mg every morning, and hydroxyzine hydrochloride 10–25 mg at nighttime.
  - **Bandaging:** Paste bandaging may be used for lichenified eczema of the limbs. It helps absorption of topical treatment and also acts as a barrier to prevent scratching.
  - **Prompt treatment of secondary infection by antibiotics:** Secondary infection of eczema may lead to exacerbation of atopic dermatitis. The causative agent for secondary infection should be identified by culture and treated with appropriate systemic antibiotics.
- **Phototherapy:**
  - **Narrow-band-UVB phototherapy:** Ultraviolet radiation (UVR) treatment—most commonly narrow-band ultraviolet B is used.
  - **Psoralen and ultraviolet A (PUVA)**
- **Systemic therapy:**
  - Systemic glucocorticosteroids should be given for severe exacerbations that do not respond to topical therapy. Generally, oral prednisolone is given in the dose of 0.5–1 mg/kg/day.
  - *Use of cyclosporin*: Cyclosporin is an immunosuppressant that inhibits production of interleukin-2 by T lymphocytes.

Lichenification

- The term lichenification is classed as a secondary skin lesion wherein the characteristic features of skin thickening, hyperpigmentation, and exaggerated skin lines are noted.
- Lichenification can be further divided into primary and secondary types wherein primary lichenification signifies lichen simplex chronicus, also known as neurodermatitis circumscripta.
- Secondary lichenification occurs in atopic dermatitis, infective eczematous dermatoses, psoriasis, psoriasiform dermatosis, xerosis, pityriasis rubra pilaris, porokeratosis, vegetative growths, anxiety, and obsessive-compulsive disorders.

TABLE 19.3: Classification of topical corticosteroids by potency.

Potency	*Class*	*Topical corticosteroid*	*Formulation*
Ultra high	I	Clobetasol propionate	Cream, 0.05%
		Diflorasone diacetate	Ointment, 0.05%
High	II	Amcinonide	Ointment, 0.1%
		Betamethasone dipropionate	Ointment, 0.05%
		Desoximetasone	Cream or ointment, 0.025%
		Fluocinonide	Cream, ointment gel, 0.05%
		Halcinonide	Cream, 0.1%
	III	Betamethasone dipropionate	Cream, 0.05%
		Betamethasone valerate	Ointment, 0.1%
		Diflorasone diacetate	Cream, 0.05%
		Triamcinolone acetonide	Ointment, 0.1%
Moderate	IV	Desoximetasone	Cream, 0.05%
		Fluocinolone acetonide	Ointment, 0.025%
		Fludroxycortide	Ointment, 0.05%
		Hydrocortisone valerate	Ointment, 0.2%
		Triamcinolone acetonide	Cream, 0.I%
	V	Betamethasone dipropionate	Lotion, 0.02%
		Betamethasone valerate	Cream, 0.1%
		Fluocinolone acetonide	Cream, 0.25%
		Fludroxycortide	Cream, 0.05%
		Hydrocortisone butyrate	Cream, 0.I%
		Hydrocortisone valerate	Cream, 0.2%
		Triamcinolone acetonide	Lotion, 0.1%
Low	VI	Betamethasone valerate	Lotion, 0.05%
		Desonide	Cream, 0.05%
		Fluocinolone acetonide	Solution, 0.01%
	VII	Dexamethasone sodium phosphate	Cream, 0.1%
		Hydrocortisone acetate	Cream, 1%
		Methylprednisolone acetate	Cream, 0.25%

Contact Dermatitis

Allergic contact eczema (Figs. 19.12A and B)

This develops as a manifestation of delayed hypersensitivity reaction following contact with antigens or haptens. Many agents can cause allergic contact eczema and common agents include nickel in costume jewelry and buckles (e.g., eczema of the earlobes and umbilicus), chromate in cement (eczema of the hands and foot), and latex in surgical rubber gloves (eczema of the hands and wrist). Allergy persists indefinitely and eczema develops at sites of contact of allergen.

During the acute phase, lesions show edema, erythema, and vesicle formation. Later, vesicles rupture producing oozing and papules and plaques appear. In the chronic phase, scaling, lichenification, and excoriations predominate.

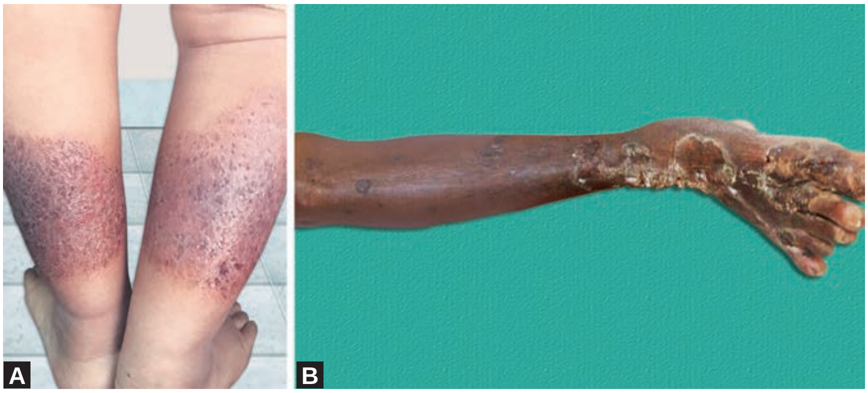
Irritant contact eczema

This type of eczema can occur in any individual and the injury is due to an inherent characteristic of compound-irritant contact dermatitis. It usually develops on the hands after repeated exposures to irritants (e.g., detergents, soaps or bleach, alkalis, and acids) and is common in housewives, cleaners, hairdressers, mechanics, and nurses. The lesions may be acute (wet and edematous) with strong irritants or chronic (dry, thickened, and scaly) with weak irritants.

Seborrheic Dermatitis

Seborrheic dermatitis is a common, chronic disorder, characterized by red scaly patches or plaques.

- **Etiology:** It is due to *Pityrosporum ovale* (also called *Malassezia furfur* in its hyphal form).
- **Sites of involvement:** Seborrheic dermatitis affects body sites rich in sebaceous glands.
- **Scalp:** It most commonly affects the scalp (recognized as severe dandruff).



FIGS. 19.12A AND B: (A) Skin lesions of symmetrical atopic dermatitis; (B) Chronic contact dermatitis.

Treatment of contact dermatitis

- Identify and avoid the contact with causative agent/irritants and use of protective gloves or clothing. In extreme cases, even changing of occupation or hobbies may be needed.
- Treatment with high-potency topical glucocorticoids.
- In cases where systemic therapy is indicated, daily oral prednisone beginning at 1 mg/kg, but usually 60 mg/day is given. It should be tapered over 2–3 weeks.

- **Facial region:** On the face, it affects the nasolabial folds, eyebrows, eyelids, and glabella. Scaling of the external auditory canal and the postauricular areas often show maceration and tenderness.
- Other sites include central chest, axilla, groin, submammary folds, and gluteal cleft.

Clinical features: Three age groups are affected by seborrheic dermatitis.

1. **In neonates**: It presents as yellowish thick crusts on the scalp **(cradle cap),** face, or groin. Normally, it improves spontaneously after a few weeks.
2. **In young adults (especially males)**: The rash is more persistent and presents as an erythematous scaling along the sides of the nose, in the eyebrows, around the eyes, and in the scalp (dandruff). It is more common in patients with **Parkinson's disease,** in those who have had cerebrovascular accidents, and in those with **HIV infection** (especially with CD4 cell count <400/mm^3).
3. **In elderly people**: It can be more severe and progress to involve large areas of the body.

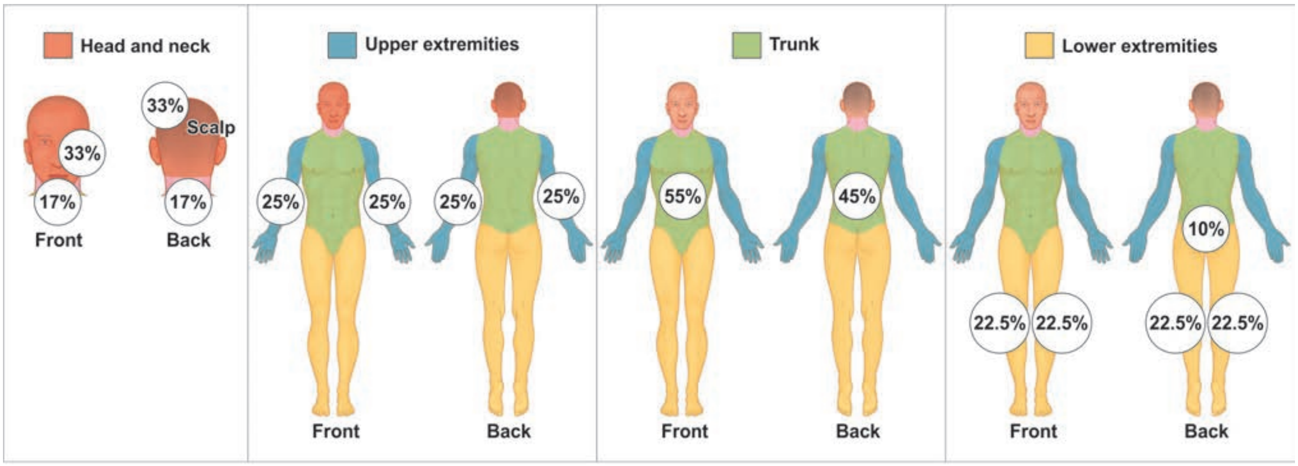
Treatment of seborrheic dermatitis

Treatment is suppressive rather than curative.

- A **combination of low-potency topical glucocorticoids** (e.g. 1% hydrocortisone applied twice daily) with a **topical antifungal cream** (e.g., miconazole or ketoconazole or Ciclopirox olamine cream applied twice daily) is often effective. Topical 0.1% tacrolimus ointment or pimecrolimus cream can also be effective.
- **Antipityrosporal agents,** such as ketoconazole shampoo and arachis oil, are useful for the scalp and beard areas. Emollients and a soap substitute may be used as adjuncts. High-potency topical glucocorticoids (betamethasone or clobetasol) are effective in cases with severe scalp involvement. However, they should not be used on the face because they may be associated with steroid-induced rosacea or atrophy.

Adverse effects of drugs used for eczema:

- **Tacrolimus:** Diabetes mellitus, drug induced thrombotic microangiopathy, hyperkalemia, metabolic acidosis, hyperuricemia.
- **Hydrocortisone:**
  - Cardiovascular—bradycardia, cardiac arrhythmia, cardiac failure, hypertrophic obstructive cardiomyopathy (HOCM), embolism
  - Dermatological—acne vulgaris, allergic dermatitis, atrophic striae, burning sensation of the skin, hyperpigmentation, hypertrichosis, hypopigmentation
  - Endocrine—adrenocortical insufficiency, Cushing syndrome, hypothalamic-pituitary-adrenal (HPA) axis suppression, hyperglycemia
  - Gastrointestinal—gastroesophageal reflux disease (GERD), hiccups, peptic ulcer
  - Hematological—leukocytosis, petechiae
- **UVB phototherapy adverse effects:**
  - Acute—sunburn or phototoxic reaction if overdosed, conjunctivitis, keratitis, provocation of photodermatoses
  - Chronic—lentigines, photoaging, actinic keratosis, melanoma



Adapted fom Home (Harmonising Outcome Measures for Eczema) EASI user guide 2016

Then, using the table below, give each respective body region a score between 0 and 6 based on the estimated percentage involvement.

% Involvement	0	1–9%	10–29%	30–49%	50–69%	70–89%	90–100%
Score	0	1	2	3	4	5	6

FIG. 19.13: Severity of eczema.

A score of 0 indicates clear or no eczema, 0.1 to 1.0 indicates almost clear. 1.1 to 7 indicates mild disease. 7.1 to 21 indicates moderate diseases, 21.1 to 50 indicates severe disease, and greater than 51 indicates very severe disease.

Pityriasis Versicolor (Tinea Versicolor)

Q. Write short essay/note on pityriasis versicolor (tinea versicolor).

- Pityriasis versicolor is a relatively common persistent, superficial skin condition caused by a common commensal lipophilic yeast—**Malassezia furfur** (also known as *Pityrosporum ovale*). The yeast is a normal inhabitant of the skin.
- **Predisposing factor:** Infection is more frequent in warmer, humid climates, and is usually more severe and persistent in the immunocompromised individuals.
- **Appearance of skin lesion (Fig. 19.14):** Typical lesion is round, scaly, oval macules on the upper trunk. It is usually hypopigmented (on dark skin) but occasionally hyperpigmented (on light skin). Hypopigmentation is more obvious after sun exposure and tanning. Sometimes, it may have raised erythematous margins. Inappropriate use of topical steroids causes spread of the lesion.
- **Sites affected** are upper back, shoulders, and chest but it also affects upper arms, neck, and rarely on the face. The lesions are more extensive in patients in tropics.
- **Other diseases associated with tinea versicolor:** Cushing's syndrome, hyperhidrosis, and altered immune status (e.g., HIV).

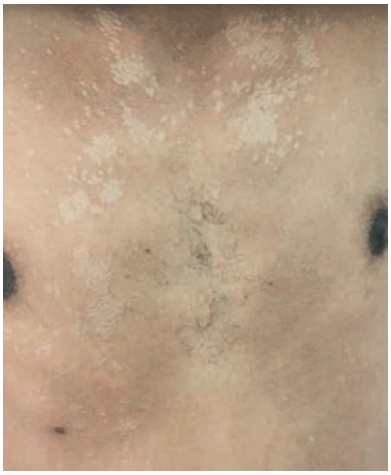


FIG. 19.14: Skin lesions of pityriasis versicolor (tinea versicolor).

Diagnosis

The diagnosis can be confirmed by:

- **Skin scraping:** It shows characteristic ***"spaghetti and meatballs"*** appearance.
- **Wood's light examination:** It shows some pigment (yellow fluorescence) in skin regions involved by tinea versicolor whereas in vitiligo, there is total loss of pigment in the affected areas.

Treatment

Topical antifungals

- Selenium sulfide or 2% ketoconazole shampoo to be applied to the affected areas of the body and removed after 30–60 minutes and repeated daily for 1 week. In resistant cases, overnight application may be useful.
- Topical imidazole (miconazole, clotrimazole, and ketoconazole) cream twice daily for 10 days

Oral antifungals

Oral itraconazole (100 mg twice daily for 1 week) is given in resistant cases. The pigmentation takes months to recover even after successful treatment. Others include ketoconazole (200 mg daily for 10 days or 400 mg/day for 2 days, though less effective), and fluconazole (150–300 mg weekly for 2–4 weeks). The condition may recur but can be retreated.

BLISTERING (BULLOUS) DISORDERS OF SKIN

Blistering skin diseases (BSDs) are skin conditions characterized by blister formation. A blister is an accumulation of fluid between cells of the epidermis or upper dermis (**Fig. 19.15**). Causes of blister formation may be genetic, physical, inflammatory, immunologic, and as a reaction to drugs. Blistering disorders are mostly due to autoimmune mechanism.

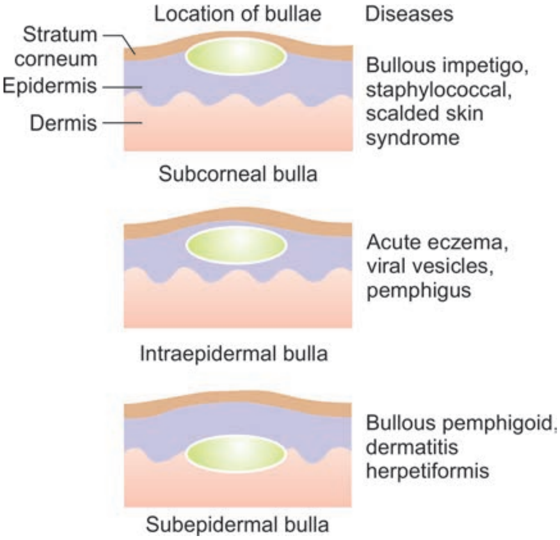
Types of Blistering Diseases (Box 19.5)

Box 19.5: Types of blistering diseases.

Genetic blistering diseases: (1) Epidermolysis bullosa and (2) Hailey–Hailey disease (benign familial pemphigus)

Immunobullous diseases:

- **Intraepidermal immunobullous diseases:** (1) Pemphigus vulgaris (PV), (2) pemphigus vegetans, (3) pemphigus foliaceus, (4) pemphigus erythematosus, and (5) paraneoplastic PV
- **Subepidermal immunobullous diseases:** (1) Bullous pemphigoid, (2) pemphigoid gestationis, (3) linear IgA disease, (4) epidermolysis bullosa acquisita, and (5) dermatitis herpetiformis



Location of bullae
Diseases
Stratum corneum
Epidermis
Dermis
Bullous impetigo, staphylococcal, scalded skin syndrome
Subcorneal bulla
Acute eczema, viral vesicles, pemphigus
Intraepidermal bulla
Bullous pemphigoid, dermatitis herpetiformis
Subepidermal bulla

FIG. 19.15: Location of bullae and few associated diseases.

Pemphigus Vulgaris

Q. DR13.1, 13.2, 13.3 Write short essay/note on etiology, clinical features, diagnosis, and treatment of pemphigus vulgaris.

Pemphigus vulgaris (PV) is a potentially fatal mucocutaneous blistering disease.

Etiology

- **Autoimmunity:** It is thought to be an autoimmune disorder. Patients with PV have IgG4 autoantibodies directed against desmosomal protein desmoglein-1 and -3 (belong to the cadherin family of calcium-dependent adhesion molecules). Desmoglein-1 and -3 are expressed in skin and mucosal surfaces. IgG4 autoantibodies are responsible for blister formation and their titer correlates with disease activity.
- **Drug-induced pemphigus:** Pemphigus may also be drug induced (e.g., sulfonamides, penicillins, and antiepileptic drugs).

Clinical features

- **Age and gender:** It predominates in patients between the fourth and sixth decades of life and both sexes are affected equally.
- **Lesions:** They typically begin on mucosal surfaces and often progress to involve the skin. Lesions consist of fragile, flaccid blisters that rupture to produce erosions in mucous membranes and skin.

Oral cavity

- **Characteristic of lesion:** Mucosal involvement (especially oral ulceration) is the most common (up to 75% of cases) presenting sign. Lesions consist of fragile, flaccid blisters that rupture to produce erosions in mucous membranes.
- **Sites:** Lesions within the oral cavity can be seen anywhere and are most often found in areas subjected to friction trauma (e.g., cheek mucosa, tongue, palate, and lower lip).

Skin lesions

- **Sites:** Typically involves scalp, face, neck, trunk, and intertriginous areas (axilla and groin).
- Skin lesions follow oral lesion and appear as **nonitchy flaccid blisters filled with clear fluid** that arises on normal skin. Blistering usually becomes widespread and is fragile. They **rapidly denude/rupture** giving rise to painful **erythematous and weeping erosions.** Erosions are often large. Intact blisters may be sparse.

Q. Write short essay/note on Nikolsky's sign.

Nikolsky's sign: It is positive. It is elicited by applying gentle manual sliding pressure to the affected skin (e.g., where a blister is located, or rub sideways over the perilesional skin or normal skin with a cotton swab or finger). A positive response is indicated by extension of the blister and/or separation of the epidermis in the area immediately and is known as Nikolsky's sign. This sign is not specific to pemphigus but is also seen in toxic epidermal necrolysis (TEN), Stevens–Johnson syndrome, staphylococcal-scalded skin syndrome, bullous impetigo, and epidermolysis bullosa. This sign is usually negative in bullous pemphigoid.

Bulla-spread phenomenon: Gentle pressure on an intact bulla forces the fluid to spread under the skin away from the site of pressure (also called ***Asboe–Hansen sign, or the "indirect Nikolsky" or "Nikolsky II" sign***).

Diagnosis

- *Skin biopsy*: Microscopically, it shows suprabasal blister due to suprabasilar (immediately above the basal cell layer) acantholysis (the dissolution or lysis of the intercellular bridges that connect squamous epithelial cells). Acantholytic cells separate from one another, lose their polyhedral shape, and appear round (tombstone appearance).
- *Direct immunofluorescence*: Lesions show a characteristic net-like pattern of intercellular IgG deposits. IgG is usually seen at all levels of the epithelium.

Treatment

- Anesthetic mouth lozenges to reduce the pain of mouth ulcers
- Fluids and electrolytes balance and nutritional support, if required
- Antibiotics to control secondary infections

Patients with moderate-to-severe PV:

- **Systemic glucocorticoids:** These are mainstay of treatment to inhibit production of the autoantibodies. These usually started on oral prednisone, 1 mg/kg/day as an early morning dose.
- **Immunosuppressive agents:** If new lesions continue to appear after 1–2 weeks of treatment with prednisone, the dose is to be increased and/or combined with other immunosuppressive agents such as azathioprine, mycophenolate mofetil, or cyclosporin, or cyclophosphamide.

- **Immunoglobulins:** One course of intravenous immunoglobulin (400 mg/kg/day for 5 days) may be a safe and effective treatment for cases resistant to steroids.

Severe/treatment-resistant disease:

Plasmapheresis [six high-volume exchanges (i.e., 2–3 L per exchange) over ~2 weeks], **IV immunoglobulin** (IVIg) (2 g/kg over 3–5 days every 6–8 weeks), or **rituximab** (375 mg/m^2 per week × 4, or 1,000 mg on days 1 and 15). The duration of therapy varies according to the level of disease activity.

Bullous Pemphigoid

Q. DR13.1, 13.2, 13.3 Write short essay/note on:

- Bullous pemphigoid or pemphigoid
- Etiology, clinical features, diagnosis, and treatment of bullous pemphigoid.

Bullous pemphigoid (BP) is the most common autoimmune subepidermal blistering disease. Mucosal involvement is rare.

Age and gender: It occurs in elderly in the fifth to seventh decades, with an average age of onset of 65 years. Males and females are equally affected.

Etiopathogenesis

Bullous pemphigoid is caused by autoantibodies against specialized proteins that are involved in adherence of basal keratinocytes to the basement membrane. These linking proteins are called **hemidesmosomes** and the so-called bullous pemphigoid antigens (BPAGs) are components of these hemidesmosomes.

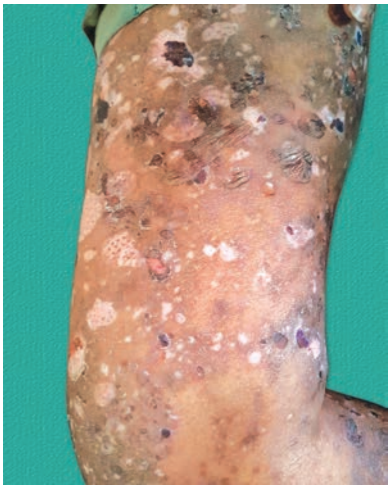


FIG. 19.16: Bullous pemphigoid.

Clinical features

Bullae (Fig. 19.16): Patient usually presents with large tense bullae anywhere on the skin but often involve flexor surfaces of the arms and legs, axilla, groin, and abdomen. The bullae may be centered on an erythematous or urticated skin. The bullae may contain hemorrhagic fluid. Pemphigoid can be very itchy. Mucosal ulceration is uncommon and when seen, it is of minor clinical significance. Nontraumatized bullae usually heal without scarring.

Diagnosis

Skin biopsy: Biopsies of skin lesion show subepidermal blisters with an eosinophil-rich inflammatory infiltrate at sites of vesicle formation and in perivascular areas.

Direct immunofluorescence: It shows linear deposits of **IgG and C3 at the dermoepidermal junction.**

Treatment

- Patients with local or mild disease can sometimes be controlled with the application of very potent topical steroids to all sites in frail elderly patients. Occasionally, it can be controlled by oral dapsone or high-dose oral minocycline or tetracyclines.
- The mainstay of treatment is systemic **glucocorticoid** (oral prednisolone 30–60 mg daily). Patients with more extensive lesions respond to systemic glucocorticoids either alone or in combination with immunosuppressive agents. Immunosuppressive agents include azathioprine, mycophenolate mofetil, or cyclophosphamide.

Intravenous immunoglobulin as a steroid-sparing therapy in BP may also be useful.

Dermatitis Herpetiformis

Q. Write short note on dermatitis herpetiformis.

- It is characterized by intensely itchy, chronic papulovesicular eruption distributed symmetrically on extensor surfaces.
- **Age:** It may start at any age. Most commonly, it occurs in 2nd, 3rd, and 4th decades of life.
- **Skin biopsy:** If a vesicle can be biopsied before it is scratched away, the microscopic examination shows a subepidermal blister, with dermal papillary collections of neutrophils (microabscesses).
- **DIF (direct immunofluorescence):** Granular **IgA** deposits in normal-appearing skin are diagnostic for DH.
- Most DH patients (not all) have an associated **gluten-sensitive enteropathy.** So, associated antiendomyseal antibodies are positive.

Treatment

- The rash responds rapidly to **dapsone** therapy.
- Gluten-free diet works very slowly.

DIFFERENCES BETWEEN PEMPHIGUS VULGARIS AND BULLOUS PEMPHIGOID

	Pemphigus vulgaris	***Bullous pemphigoid***
Epidemiology	Average age 40–60	Elderly >60
Time course	Chronic, relapsing	Chronic, relapsing
Symptoms	Painful	Itchy
Mucosal involvement	Common	10–30%
Bullae	Flaccid, many already ruptured	Tense
Nikolsky sign	Positive	Negative
Antibodies	Autoantibodies against desmoglein 1 and 3	Hemidesmosomal bullous pemphigoid antigens BP230 and BP180
Histology	Suprabasilar clefting, "row of tombstone" pattern of basal keratinocytes	Subepidermal clefting
Direct immunofluorescence	Intercellular IgG deposits	Linear IgG deposits at basement membrane
Treatment	Systemic glucocorticoids ± nonsteroidal immunomodulator	Systemic or topical glucocorticoids ± nonsteroidal immunomodulator

REACTIVE DISORDERS OF SKIN

Erythema Multiforme

Q. Write short essay/note on precipitating causes, clinical manifestations, and management of erythema multiforme.

- Erythema multiforme (EM) is an uncommon acute, self-limiting, recurrent cutaneous and/or mucocutaneous blistering eruption that occurs in individuals of any age.
- Eruptions are characterized by target-shaped plaques commonly over extremities and face.

Causes

Erythema multiforme can be triggered by variety of factors (**Box 19.6**).

Box 19.6: Precipitating factors in erythema multiforme.

1. **Infections:**
   - Viral, e.g., herpes simplex, orf, infectious mononucleosis, hepatitis B, and HIV
   - *Mycoplasma* and other bacterial infections (e.g., typhoid)
   - Fungal, e.g., histoplasmosis and coccidioidomycosis
   - Rickettsia
2. **Exposure to drugs:** For example, sulfonamides, penicillins, barbiturates salicylates, hydantoins, antimalarials, and carbamazepine
3. **Systemic disease:**
   - Sarcoidosis
   - Malignancy (carcinomas and lymphomas)
   - Collagen vascular diseases [Systemic lupus erythematosus (Rowell's syndrome), Wegener's granulomatosis, dermatomyositis, and polyarteritis nodosa]
4. **Other:** Radiotherapy, pregnancy

Pathogenesis

Immune-mediated disease: It is characterized by keratinocyte injury caused by CD8$^+$ cytotoxic T lymphocytes in the skin. The CD8$^+$ cytotoxic T cells are found in the central portion of the lesions, and CD4$^+$ helper T cell and Langerhans cells are found in the peripheral portions. The epidermal antigens causing the disease are not known.

Classification

See **Box 19.7**.

Box 19.7: Classification of erythema multiforme (EM).

- **EM Minor**: Cutaneous without mucous involvement
- **EM Major (EMM)**: Cutaneous + mucous involvement
- **Mucosal EM**: Fuch's ectodermosis pluriorificialis
- **HAEM**: Herpes-associated EM
- **MPAEM**: Mycoplasma-associated EM

Clinical Features of Erythema Multiforme

- Male:Female = 3:2
- Occurs in the young/adolescents
- About 50% of patients give history of preceding herpetic infection.
- Associated with HLA – DQB1 * 0301 Allele

Elementary skin lesions

Multiforme: As the name implies, it presents with a diverse array of lesions (multiforme), including macules, papules, vesicles, and bullae.

Distribution of skin lesions (topography)

- Lesions are symmetrical, acral, and centripetal in distribution
- *Extensor aspect*: Extremities > face > neck > trunk
- Predilection to sun-exposed areas/Koebnerization present.

Characteristic lesion

Q. Write short essay/note on target lesions, iris lesions, and bull's eye lesions of erythema multiforme.

- **Classic target lesion (Fig. 19.17):** It consists of **three concentric distinct zones/ rings** of different colors—a **dark central circular dusky red** (darker red) zone is surrounded by an **intermediate light rim** (white), which in turn is encircled by a **outermost red zone** (iris lesions). Central circular zone may show bulla formation or crust. The lesion may resemble a **"bull's eye".**
- Larger lesions show central bulla and marginal ring of vesicles: **Herpes iris of Bateman.**

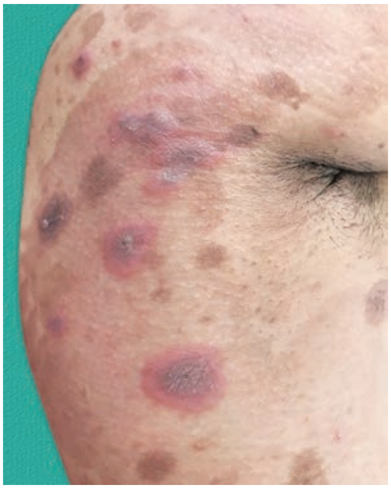

FIG. 19.17: Erythema multiforme with target lesion.

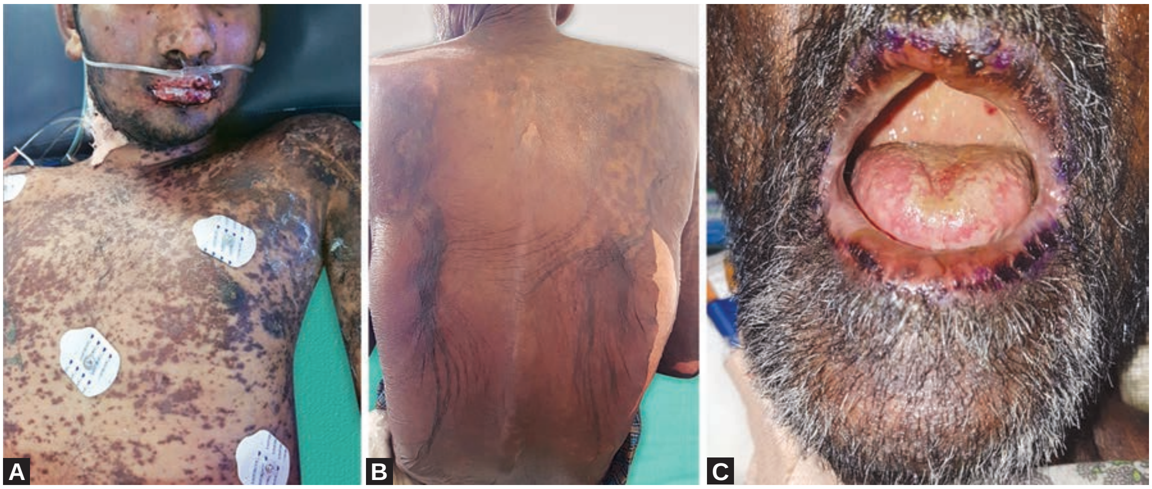
Mucosal lesions

Mucosal (oral mucosa) involvement is usually absent and, when present, lesions are few in number and mildly symptomatic.

Stevens–Johnson Syndrome (Figs. 19.18A to C)

Q. Write short essay/note on Stevens–Johnson syndrome.

- Stevens–Johnson syndrome (SJS) is a rare, acute, and life-threatening mucocutaneous disease with systemic involvement and is nearly always drug-related.
- SJS is a "minor form of TEN" with <10% body surface area (BSA) detachment
- *Overlapping Stevens–Johnson syndrome/toxic epidermal necrolysis (SJS/TEN)*: Detachment of 10–30% BSA
- *Toxic epidermal necrolysis (TEN)*: **Detachment of >30% BSA**



FIGS. 19.18A TO C: (A) Stevens–Johnson syndrome (SJS)/toxic epidermal necrolysis (TEN); (B) Toxic epidermal necrolysis; (C) Oral lesions in SJS/TEN.

Clinical features of Stevens–Johnson syndrome are listed in **Table 19.4**.

Mortality rate in SJS: 1–5%

TABLE 19.4: Clinical signs and symptoms of Stevens–Johnson syndrome/toxic epidermal necrolysis.

Cutaneous	*Mucous membrane*[a]	*Extracutaneous*
Initial phase: ➢ Erythematous, dusky red, flat, and atypical targetoid macules ➢ Symmetrical lesions distributed on the face/trunk/proximal part of limbs. It can spread to entire body *Later phase*: ➢ Lesions progressively coalesce and evolve into flaccid blisters ➢ Detachment of epidermis	➢ *Ocular:* Edema of eyelid, redness, photophobia, discharge, lacrimation, and corneal scarring ➢ *Buccal:* Erosive hemorrhagic lesions, grayish–white pseudomembranes, and crust on lips ➢ *Genital:* Erosive hemorrhagic lesions and painful urination	➢ *Nonspecific*: Fever, pain, and weakness ➢ *Respiratory*[b]: Respiratory distress ➢ *Gastrointestinal*: Diarrhea, nausea, malabsorption, and perforation of colon, melena ➢ *Renalb:* Proteinuria, hematuria, and microalbuminuria

a—normally involves at least two sites; *b*—lower occurrence in SJS compared to TEN

Toxic Epidermal Necrolysis (Lyell's Syndrome)

Q. Write short essay/note on toxic epidermal necrolysis.

- Toxic epidermal necrolysis is characterized by diffuse necrosis and sloughing of skin and mucosal epithelial surfaces. It begins with severe mucosal erosions and progresses to diffuse, generalized detachment of the skin epidermis.
- Nikolsky sign often positive, i.e., sliding pressure from a finger on normal-looking epidermis dislodges the epidermis.
- No target lesions seen
- *Mortality rate in TEN*: High (30%)

Management

Treatment of erythema multiforme

- Management of the precipitating factors/causes. If a drug is suspected, it must be discontinued and precipitating infection should be treated.
- Treatment of EM otherwise is nonspecific.
- Severe cases may require systemic corticosteroids.
- Oral acyclovir early reduces the number and duration of lesions.
- Chronic antiviral treatment with acyclovir (400 mg twice daily for 6 months) in herpes-associated outbreaks in patients with recurrent erythema multiforme

Treatment of SJS (Stevens–Johnson syndrome) and TEN (toxic epidermal necrolysis)

- Maintain the fluid and electrolyte balance
- Manage oral mucosal lesions with mouthwashes. Topical anesthetics may reduce pain and allow the patient to take in fluids
- Area of denuded skin should be covered with compresses of saline
- ***Systemic corticosteroid*** *is* ***contraindicated*** *in Stevens–Johnson syndrome*
- Treatment of toxic epidermal necrolysis is very difficult, but intravenous immune globulin (2–3 g/kg over a period of 2–5 days) may improve the prognosis.

DRESS Syndrome

Q. Write a short note on DRESS syndrome.

"Drug reaction with eosinophilia and systemic symptoms"

It is potentially life-threatening drug-induced, hypersensitivity reaction that includes skin eruption, hematologic abnormalities, lymphadenopathy, and internal organ damage.

Etiology and Risk Factors

Frequently reported		*Also reported*	
➢ **Antiepileptics (carbamazepine, lamotrigine, phenytoin, phenobarbital)** ➢ **Allopurinol**	➢ **Sulfonamides** ➢ Dapsone ➢ Minocycline ➢ Vancomycin	➢ Phenindione ➢ Beta lactams ➢ Olanzapine ➢ Febuxostat (DRESS with renal involvement)	➢ Nevirapine ➢ Oxcarbazepine ➢ Strontium ranelate ➢ Lenalidomide

Clinical Features

Systemic symptoms:

- 2–6 weeks after the initiation of the offending drug
- Fever (38–40°)
- Malaise
- *Lymphadenopathy*: Tender and slightly enlarged. Biopsy shows features of viral lymphadenopathy or benign lymphoid hyperplasia.

Visceral involvement: At least one organ involved in 90% patients—

- *Liver*: Hepatomegaly, jaundice, and asymptomatic hepatitis
- *Kidney*: Acute interstitial nephritis
- *Lung*: Nonspecific symptoms (cough, fever, and tachypnea/dyspnea). CXR/CT—evidence of interstitial pneumonitis and/or pleural effusion
- *Cardiac*: Eosinophilic myocarditis and pericarditis
- *Gastrointestinal tract (GIT)*: Diarrhea, mucosal erosions, bleeding, and pancreatitis
- *Thyroid*: Autoimmune thyroiditis

- *Nervous system*: Encephalitis, meningitis, and polyneuritis
- Myositis and increase in CPK
- *Eye*: Uveitis
- It rarely has been associated with shock/multiorgan failure and DIC.

Skin:

- Starts as a morbilliform eruption and progresses rapidly to a diffuse/confluent erythema with follicular accentuation
- DRESS is likely when the eruption involves >50% of BSA and/or includes two or more of facial edema/infiltrated lesions/scaling and purpura. Percentage of BSA involved is a marker of disease severity.
- In 20–30%, erythema can progress to exfoliative dermatitis.
- Face, upper part of trunk and extremities involved initially.
- Facial edema in 50% cases. It is symmetric, persistent, and associated with erythema.
- *Mucosa*: Inflamed, usually at one site only, does not progress to erosions.

Laboratory Features

Complete blood count (CBC)	Leukocytosis, peripheral eosinophilia, atypical lymphocytosis
Liver function test (LFT)	Alanine aminotransferase > 2 times the upper limit Alkaline phosphatase >1.5 times the upper limit
Renal function test (RFT)	Moderate increase in serum creatinine Low-grade proteinuria Abnormal urinary sediment with eosinophils
Serology	To exclude viral hepatitis in cases with deranged LFTs
Skin biopsy	Mild spongiosis, lymphocytic infiltrate in the superficial dermis with eosinophils and dermal edema

Management

- **Drug withdrawal and avoidance of introducing new medications during the course**
- Fluid, electrolyte, and nutritional support
- Warm, humid environment, and skincare with warm baths/wet dressings and emollients
- Patients without evidence of renal/pulmonary involvement and only modest elevation of liver transaminases (<3 times) can be treated symptomatically.
  - **For pruritus and skin inflammation, high-potency topical steroids (betamethasone, clobetasol, fluocinonide, halobetasol) are applied 2 times/day for 1 week.**
- Patients with severe organ involvement:
  - *Acute hepatitis*: Withdrawal of offending drug and follow-up by serial LFT. Liver transplant in cases of acute liver failure.
  - **Moderate-to-high dose of systemic corticosteroids in severe lung involvement** (dyspnea, abnormal CXR, and hypoxemia) and severe renal involvement (creatinine >150% basal level, proteinuria, or hematuria).
  - Given till clinical improvement or normalization of laboratories and then tapered over 8–12 weeks.
- **Cyclosporine: Second-line therapy for those who do not respond to steroids or if steroids are contraindicated.**

PIGMENTARY DISORDERS OF SKIN

Hypopigmentation

Q. List the differential diagnosis of hypopigmented cutaneous lesions/hypopigmentation.

Causes of Hypopigmentation

See **Box 19.8**.

Box 19.8: Causes of hypopigmentation and/or depigmentation.

Genetic
- Albinism
- Piebaldism
- Phenylketonuria
- Waardenburg's syndrome
- Chediak-Higashi syndrome
- Tuberous sclerosis

Endocrine
- Hypopituitarism

Chemical
- Contact with substituted phenols (in rubber industry) chloroquine and hydroxychloroquine

Postinflammatory
- Eczema
- Pityriasis alba
- Psoriasis
- Sarcoidosis
- Lupus erythematosus
- Lichen sclerosus et atrophicus
- Cryotherapy

Infections
- Leprosy
- Pityriasis versicolor
- Syphilis, yaws and pinta

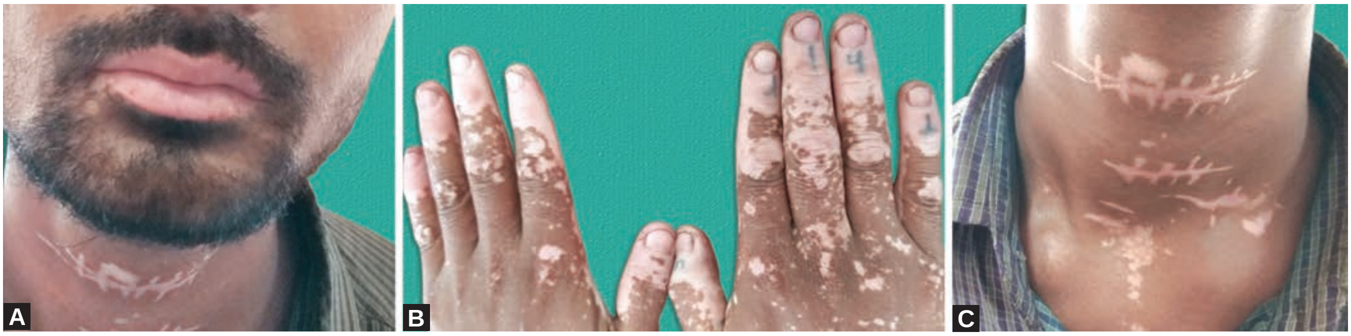
Tumors
- Halo nevus
- Malignant melanoma

Miscellaneous
- Vitiligo
- Idiopathic guttate hypomelanosis

Vitiligo

Q. DR2.1, 2.2 Write short note on etiology, clinical features, and treatment of vitiligo.

Vitiligo is a common, slowly progressive acquired condition caused by focal loss of melanocytes within the skin resulting in the development of well-circumscribed patches of hypopigmentation (**Figs. 19.19A to C**).



FIGS. 19.19A TO C: (A) Vitiligo; (B) Acral vitiligo; (C) Koebner phenomenon in vitiligo.

Classification

See **Box 19.9**.

Clinical Features

Nonsegmental vitiligo (NSV)

- It presents as small, depigmented macule that may enlarge and coalesce into larger patches.
- NSV is further divided into subtypes based upon the distribution of skin lesions (i.e., generalized, acral or acrofacial, mucosal, localized, universal, and mixed pattern).
- It is often symmetrical and occurs mainly around body orifices (around the eyes, nose, lips, and genitalia), hands, feet, flexor surface of the wrists, ankles, elbows, knees, and major body folds.
- The hair of the scalp, beard, eyebrows, and lashes (leukotrichia) may also show depigmentation.
- **Vitiligo fulminans/galloping vitiligo:** Rapid downhill course with rapid progression of skin lesions
- Patients are very susceptible to sunburn.
- Nonsegmental vitiligo can spread by **Koebner phenomenon (Fig. 19.19C).** *Other skin conditions that spread by Koebner phenomenon include psoriasis, molluscum contagiosum, warts, EM, and lichen planus.*

Segmental vitiligo

It is **restricted to one part** of the body. The patches of depigmentation are sharply defined. Spotty perifollicular pigment may be seen within the depigmentation. **Sensation in the depigmented patches is normal** (unlike in tuberculoid leprosy). Wood's light examination shows the contrast between pigmented and nonpigmented skin.

Box 19.9: Classification of vitiligo.

Localized
- **Focal vitiligo:** One or more macules in one area not clearly in a segment
- **Segmental vitiligo:** Number of macules in unilateral segment of the body (stops abruptly at midline)
- **Mucosal vitiligo:** Affects lips, oral cavity, and genitalia

Generalized
- **Acrofacial vitiligo:** Lesions on the acral (hand and feet) and face (perioral)
- **Vitiligo vulgaris:** Multiple macules bilaterally symmetrically scattered
- **Lip–tip vitiligo:** Tips of digits and lips only
- **Mixed:** Any combination of the above
- **Universal vitiligo:** Complete or near complete depigmentation of the body

Box 19.10: Vitiligo association with other diseases.

- Autoimmune thyroiditis
- Addison's disease
- Pernicious anemia
- Diabetes mellitus
- **Vogt–Koyanagi–Harada syndrome**: Vitiligo, poliosis, uveitis, alopecia, meningismus, and hearing difficulties
- **Alezzandrini syndrome:** Unilateral facial vitiligo, unilateral retinal degeneration, poliosis, and hearing loss
- **Kabuki syndrome:** Developmental delay, facial dysmorphism, skeletal and visceral anomalies

Trichrome vitiligo (vitiligo gradate): Presence of tan-colored zone in-between normal skin and the depigmented macule. Sometimes, a fourth color dark brown is present at sites of perifollicular repigmentation–**quadrichrome vitiligo.**

Association of vitiligo with other diseases

See **Box 19.10**.

Management

- Protect the patches from excessive sun exposure with clothing or sunscreen to avoid sunburn.
- **Treatment:** Often unsatisfactory

Topical treatment

It includes the use of potent topical corticosteroids and topical immunomodulators (e.g., calcineurin-inhibitors tacrolimus 0.1% ointment especially on the face).

Phototherapy

- Topical psoralen plus ultraviolet-A (UV-A) phototherapy (PUVA therapy) is a most effective repigmentary treatment available for nonsegmental generalized vitiligo.
- *Narrow-band UVB (NB-UVB) phototherapy*: It is the treatment of choice for active, generalized vitiligo. Cosmetic results are better and side effects are less than PUVA.
- Topical application of corticosteroids along with UVA exposure is often effective.
- Autologous melanocyte transfer is effective for treating stable, focal vitiligo.
- Extensive vitiligo may be treated with removal of pigment from the remaining normally pigmented skin by using bleaching creams (e.g., monobenzylether of hydroquinone and 4-methoxy-phenol).
- Human placental extract and calcipotriol have been tried.
- **Systemic treatment (Box 19.11)**
- **Surgical treatment (Box 19.12)**

Pityriasis Alba

- Common skin disorder in children that is usually evident before puberty.
- **Cause:** Not known, however, there is often a history of atopy.

Clinical Features

Hypopigmented patches or macules with slight scale, mainly on the face and less frequently on the neck, trunk, and extremities. No permanent damage to the skin. Often improves after puberty.

Treatment: Use of lubricants and mild topical steroids

Inherited Hypopigmentation Disorders

Q. Write short note on inherited hypopigmentation disorders.

Albinism

- Autosomal recessive inherited disorder
- Genetic defect in melanin synthesis and normal melanocyte number and structure
- Mutation in tyrosinase gene
- Affected individual will be born with white hair and skin and blue eyes (retinal pigment epithelium involved).
- Selenium deficiency in the setting of total parental nutrition can lead to **pseudoalbinism.**

Box 19.11: Systemic treatment for vitiligo.

- Psoralen and UV-A
- Corticosteroids
- Immunomodulators (cyclosporine, levamisole, and azathioprine)
- Phenylalanine plus UV-A
- Khellin
- Antioxidants
- Monobenzyl ether of hydroquinone (monobenzone)

Box 19.12: Surgical treatment for vitiligo.

- Punch grafting
- Split skin thickness grafting
- Blister grafting
- Melanocyte culture and transplantation
- Tattooing

Box 19.13: Conditions associated with increased pigmentation.

- Melasma
- Freckles (ephelides)
- Lentigines (NAME syndrome and Leopard syndrome)
- Peutz–Jeghers syndrome

Piebaldism

- Rare autosomal dominant disease
- Congenital **white forelock**
- Hyperpigmented macules within the amelanotic macules and normally pigmented skin are characteristic.

Waardenburg Syndrome

Autosomal dominant disorder characterized by white forelock, heterochromia iridis, and hypomelanotic macules.

Conditions Associated with Increased Pigmentation (Box 19.13)

Q. List the differential diagnosis for hyperpigmentation.

Systemic Diseases Causing Hyperpigmentation (Table 19.5)

TABLE 19.5: Systemic diseases causing hyperpigmentation.

Causes of increased melanin production		
Acquired	***Congenital/Inherited***	***Non-melanin causes***
➢ Melasma	➢ Mongolian spots	➢ Primary hemochromatosis
➢ Post-inflammatory pigmentation	➢ Nevus of Ota	➢ Hepatic cirrhosis
➢ Solar lentigines	➢ Nevus of Ito	➢ Chronic renal failure
➢ Ephelides	➢ Spindle cell naevus	➢ Alkaptonuria
➢ Lichen planus	➢ Blue nevus	➢ Lamellar ichthyosis
➢ Fixed drug eruption	➢ Halo nevus	➢ Epidermolytic hyperkeratosis
➢ Erythromelanosis follicularis faciei et colli	➢ Café au lait	➢ Drug and heavy metal toxicity
➢ Pellagra	➢ Peutz-Jeghers syndrome	➢ Canthaxanthin
➢ Poikiloderma of Civatte	➢ Albright syndrome	➢ Pituitary tumors
➢ Riehl's melanosis		

SKIN TUMORS

Q. Write short essay/answer on benign, premalignant conditions of the skin.

Benign and Premalignant Lesions of Skin (Table 19.6)

TABLE 19.6: Benign and premalignant lesions of skin.

Benign conditions		***Premalignant conditions***
➢ Ephelide	➢ Seborrheic keratosis	➢ Bowen's disease
➢ Melanocytic nevi	➢ Squamous cell papilloma	➢ Keratoacanthoma
➢ Granuloma telangiectaticum	➢ Warts	➢ Marjolin's ulcer
➢ Hemangioma of skin	➢ Skin tags (acrochordons)	➢ Paget's disease of the nipple
➢ Dermatofibroma	➢ Pyogenic granuloma	➢ Senile keratosis/actinic keratosis
➢ Papilloma	➢ Keloids	➢ Erythroplasia of Queyrat

Malignant Skin Tumors

Q. Write short essay/answer on common malignant skin tumors.

Malignant tumor of skin is the most common malignancy in fair-skinned populations.

Categories

See **Table 19.7**.

TABLE 19.7: List of malignant skin tumors.

Common malignant tumors	***Uncommon malignant tumors***
➢ Basal cell carcinoma ➢ Squamous cell carcinoma and its precursor Bowen's diseases	➢ Primary: – Malignant melanoma – Cutaneous T-cell lymphomas (e.g., mycosis fungoides) – Kaposi sarcoma – Apocrine carcinoma of the skin ➢ Metastasis

Etiology and Pathogenesis of Skin Malignancy

- **Sun exposure**: UVR (ultraviolet radiation) is the main environmental risk factor for skin cancer.
- **Genetic predispositions:**
  - Xeroderma pigmentosum
  - Basal cell nevus (Gorlin's) syndrome
- **Cutaneous immune surveillance:** Immunosuppressed organ transplant recipients have an increased risk of skin cancer, particularly SCC (squamous cell carcinoma). Patients who have received high numbers of PUVA treatments (>150), which are immunosuppressive, are also at increased risk of skin cancer, particularly SCC.
- **Chronic inflammation:** It is also a risk factor for SCC, which may arise in chronic skin ulcers/scars.

Basal Cell Carcinoma (Rodent Ulcer)

Basal cell carcinomas (BCC) are the most common slow-growing **invasive** malignant skin tumor that rarely metastasizes.

Types of Basal Cell Carcinoma

See **Box 19.14**.

Box 19.14: Types of basal cell carcinoma (BCC).

- Superficial BCC
- Nodular BCC, rodent type (most common type—75%)
- Pigmented BCC
- Sclerosing or morphea form BCC
- Metaphysical
- Recurrent BCC
- Cystic BCC

Clinical Presentation

- Incidence of BCCs increases with age on exposed sites and males are more commonly affected.
- **Sites:** Occur at **sun-exposed sites** and in fair-skinned people. Usual site is **above a line drawn from angle of mouth to the pinna of the ear.**

- Appear as a slow-growing **pearly papules** or nodule (or rarely be cystic), often containing prominent, dilated subepidermal blood vessels (telangiectasia).
- Advanced tumors **may ulcerate** to form a crater with a rolled, pearly edge. They **locally invade and erode the underlying bone or facial sinuses like a rodent** and are known as **rodent ulcers.** Crusting and bleeding in the center of the tumor is frequently seen.
- They are 10–20 times more common in the chronically immunosuppressed solid organ transplant recipients.

Squamous Cell Carcinoma

- **Second most common skin cancer** arising **on sun-exposed sites**
- More aggressive than basal cell carcinoma, as it can metastasize if left untreated
- **Sex:** More **common in** elderly **men** than in women
- **Clinical presentation:** Appear as sharply defined, red, scaling plaques

Management/Treatment

Basal cell carcinoma rarely metastasizes. Hence, a metastatic work-up is usually not required.

- **Surgical therapy:**
  - **Surgical excision** with controlled borders is often the treatment of choice and recurrence rates are lowest.
  - **Mohs' micrographic surgery**
- **Nonsurgical therapies:**
  - Topical photodynamic therapy and topical 5% imiquimod cream and 5-fluorouracil
  - *Cryotherapy*: It is a destructive treatment that uses liquid nitrogen
  - Radiotherapy
  - Hedgehog pathway inhibitors (vismodegib) for advanced inoperable BCC
  - *Curettage and cautery*: Occasionally can be used in older patients

Risk Factors

See **Box 19.15**.

Clinical Features

- **Sites:** Usually occurs on chronically sun-exposed portions of the skin, such as bald scalp, tops of ears, face, lower lip, and back of hands.
- **Appearance:** Depends on histological grading. Well-differentiated tumors present as keratotic nodules, whereas poorly differentiated tumors tend to be ill defined and infiltrative, often-warty nodule or plaque that may ulcerate.
- **Behavior:** They can grow very rapidly. SCC has metastatic potential.

Box 19.15: Risk factors for squamous cell carcinoma of skin.

- *Precursors of SCC*: Solar/actinic keratoses or Bowen's disease
- *Industrial carcinogens*: Tars and oils
- Chronic nonhealing skin ulcers, e.g., chronic osteomyelitis
- Old burn scars (e.g., Marjolin's ulcers)
- Ingestion of arsenicals
- Ionizing radiation or previous X-ray therapy
- Tobacco and betel nut chewing in the oral cavity
- Chronic venous ulcers and discoid lupus erythematosus

Management

- **Early diagnosis** is important. **Regional lymph nodes** should be routinely examined particularly for high-risk tumors arising on lips, ears, perigenital regions, or tumor developing at sites of chronic ulceration, burn scars, or sites of previous radiotherapy.
- **Complete surgical excision** is the usual treatment of choice. Excision with a 3–4-mm margin has a cure rate of about 90–95% for most SCC.
- **Other options:**
  - *Curettage and cautery*: Curettage should be avoided and is reserved for small, low-risk lesions
  - *Radiotherapy*: If surgery is not feasible
  - **Medical management** is not usually considered for invasive SCC. These include photodynamic therapy, systemic retinoids, imiquimod and other immunomodulators, new formulations of 5-fluorouracil, diclofenac in hyaluronic acid gel, and ingenol mebutate.

Malignant Melanoma

Malignant melanoma is a **relatively common** and most serious malignant tumor of epidermal melanocytes. Melanoma has metastatic potential, which can occur early and it causes deaths even in young individual.

Etiology and Pathogenesis

Predisposing factors

A. **Sun exposure:**
   - **Melanomas most commonly develop on sun-exposed surfaces,** particularly the upper back in men and the back and legs in women.
   - **Lightly pigmented** (pale/fair skinned) **individuals** are at **greater risk** than darkly pigmented individuals. Other environmental factors may also contribute to risk.

B. **Inherited genes:**
   About 10–15% of melanomas are familial and the genetic abnormalities are:
   Mutations in tumor suppressor gene: *CDKN2A* gene, RB gene, PTEN gene, mutations of NRAS and BRAF

C. **Other risk factors:** These include multiple melanocytic nevi (>50), sun sensitivity, immunosuppression, giant congenital melanocytic nevi, lentigo maligna, and a family history of malignant melanoma.

Box 19.16: Classification of malignant melanoma of skin.

- **Melanoma without metastatic potential (noninvasive):**
  - Melanoma in situ
  - Lentigo maligna
- **Melanoma with invasive potential:**
  - Superficial spreading melanoma
  - Nodular melanoma
  - Acral lentiginous melanoma
  - Lentigo maligna melanoma
  - Subungual melanoma

TABLE 19.8: Clinical criteria for the diagnosis of malignant melanoma.

ABCDE features of malignant melanoma:	
Asymmetry of mole	**D**iameter >6 mm
Border irregularity	**E**levation irregular
Color variegation	(+ Loss of skin markings)
The Glasgow 7-point checklist	
Major criteria	***Minor criteria***
Change in size	Diameter >6 mm
Change in shape	Inflammation
Change in color	Mild itch or altered sensation
	Oozing or bleeding

Clinical Features

Age and gender: It can occur at any age and either sex, but typically affects the leg in females and back in males. It is rare before puberty.

Sites

- **Skin:** It is the most common site and may develop in the trunk, leg, face, sole, palm, and nail beds.
- **Other sites:** Oral and anogenital mucosal surfaces, esophagus, leptomeninges, eye, and the substantia nigra.

Classification of Malignant Melanoma of Skin (Box 19.16)

Clinical signs that help to distinguish malignant from benign moles are presented in **Table 19.8**.

Management/Treatment

- **Surgical excision:** For local disease, surgical excision is the only curative treatment.
  - **Metastatic disease:** If there is sentinel node metastasis, surgical resection of lymph nodes, isolated limb perfusion, radiotherapy, immunotherapy (peginterferon α-2b, ipilimumab (anti-CTLA-4), vemurafenib, dabrafenib (BRAF inhibitor), trametinib (MEK inhibitor), pembrolizumab (PD-1 blocker), and chemotherapy may be required.

Mycosis Fungoides

Mycosis fungoides (MF) is a cutaneous lymphoma of mature CD4$^+$ T-cells. This is the most common cutaneous T-cell lymphoma. Not all cutaneous T-cell lymphomas are MF.

- Incidence—3 per million (0.29 per 100,000 population in USA) and 2% of all new cases of NHL
- Age—older adults (55–60 years)
- Male:Female—2:1

Clinical Features

Mycosis fungoides patches are usually distributed in sun-shielded areas such as those covered by a bathing suit or intertriginous regions. The cardinal features of MF are infiltration of epidermis and then dermis by atypical cerebriform lymphoid cells—**Pautrier's microabscess.** It is a chronic, slowly progressive disease that evolves from patch stage to plaque stage and subsequently to nodule/tumor stage. A diagnosis of **Sézary syndrome** is made when there is high number of these cells circulating in the peripheral blood in the presence of a lymphadenopathy and cutaneous erythroderma occupying >80% of the body surface area.

Chemotherapy, retinoids, electron beam therapy, and photochemotherapy are used in the treatment.

PHAKOMATOSES

Neurocutaneous Syndromes

Q. Write short note on neurocutaneous syndromes.

- They are group of inherited syndromes characterized by involvement of the brain and skin (sometimes retina).
- Phakomatoses (or neuro-oculocutaneous syndromes) are multisystem disorders that have characteristic central nervous system, ocular and cutaneous lesions (embryologically all originate from ectoderm) of variable severity.

Common Neurocutaneous Syndromes (Box 19.17)

Box 19.17: Common neurocutaneous syndromes.

- Neurofibromatosis I and II
- Tuberous sclerosis
- Von Hippel–Lindau disease
- Sturge–Weber syndrome
- Klippel–Trenaunay–Weber syndrome
- Osler–Weber–Rendu syndrome
- Wyburn–Mason syndrome
- Linear sebaceous nevus syndrome
- Neurocutaneous melanosis
- Waardenburg syndrome type 1 and 2
- Fabry's disease
- Lentiginosis, deafness, and cardiopathy syndrome
- Hypomelanosis of Ito
- Ataxia–telangiectasia (Louis–Bar syndrome)
- Xeroderma pigmentosum (**Fig. 19.20**)
- Cockayne's syndrome
- Rothmund–Thomson syndrome
- Sjögren–Larsson syndrome
- Neuroichthyosis
- Werner syndrome and Progeria
- Incontinentia pigmenti
- Neurocutaneous melanosis
- Retinal-neurocutaneous cavernous hemangioma syndrome (Weskamp–Cotlier syndrome)

Neurofibromatosis type 1

Q. Write short note on neurofibromatosis.

- **Synonyms:** von Recklinghausen disease and Watson disease
- An autosomal-dominant neurogenetic disorder
- NF1 affects about 1 in 3000 people. Neurofibromatosis type I (NF1) is caused by mutation in the neurofibromin gene located on chromosome 17, at the band q11.2.

Diagnostic Criteria for Neurofibromatosis Type 1 (Box 19.18): Three subtypes of neurofibromas exist: Cutaneous, subcutaneous, and plexiform. Freckles can be present since birth or sometimes appear later in life especially in the intertriginous region **(Crowe's sign).**

Button hole sign: Molluscum fibrosum—small, superficial, soft, skin-colored to darker, dome-shaped nodules, which can be pushed through a defect in the skin.

Neurofibromatosis type 2

- Neurofibromatosis type 2 (NF2) is associated with abnormalities of the *NF2* gene, which is located on chromosome 22.
- The *NF2* gene produces merlin, also known as schwannomin, a cell membrane-related protein that acts as a tumor suppressor. NF2 has an estimated birth frequency of 1 in 33,000 to 40,000.

Box 19.18: Diagnostic criteria for neurofibromatosis type 1.

Two or more of the following clinical features must be present:

- Six or more café-au-lait macules of >5 mm in greatest diameter in prepubertal individuals, and >15 mm in greatest diameter in postpubertal individuals
- Two or more neurofibromas of any type (**Fig. 19.21**) or one plexiform neurofibroma
- Freckling in the axillary or inguinal regions
- Optic glioma
- Two or more iris hamartomas (Lisch nodules) (**Fig. 19.22**)
- Distinctive bony lesion, such as sphenoid dysplasia, or thinning of the long bone cortex with or without pseu- doarthrosis
- A first-degree relative (parent, sibling, or offspring) with NF1 based on the above criteria

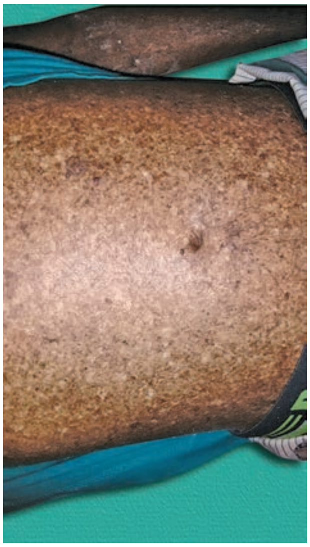


FIG. 19.20: Xeroderma pigmentosum.

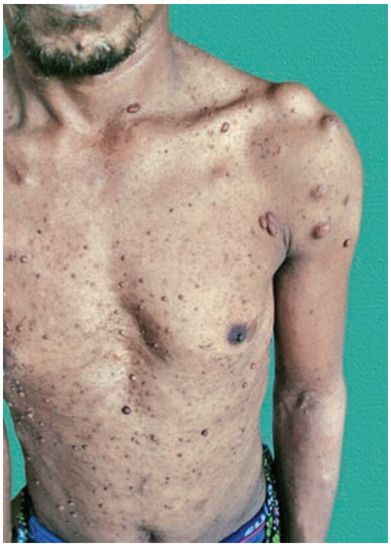

FIG. 19.21: Neurofibromatosis.

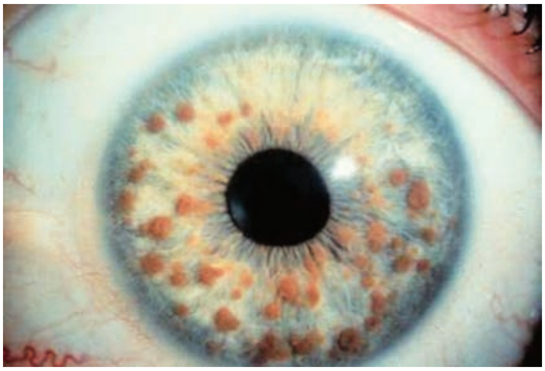

FIG. 19.22: Iris nodules (Lisch nodules) in neurofibromatosis.

Box 19.19: Diagnostic criteria for neurofibromatosis type 2.

- Bilateral vestibular schwannomas
- A first-degree relative with NF2:
  - Unilateral vestibular schwannoma or
  - Any two of—meningioma, schwannoma, glioma, neurofibroma, and posterior subcapsular lenticular opacities*
- Unilateral vestibular schwannoma
  - Any two of—meningioma, schwannoma, glioma, neurofibroma, and posterior subcapsular lenticular opacities*
- Multiple meningiomas
  - Unilateral vestibular schwannoma or
  - Any two of—schwannoma, glioma, neurofibroma, and cataract

*Any two of = Two individual tumors or cataract.

Diagnostic criteria for NF2 are listed in Box 19.19.

Tuberous Sclerosis

Q. Write short note on tuberous sclerosis.

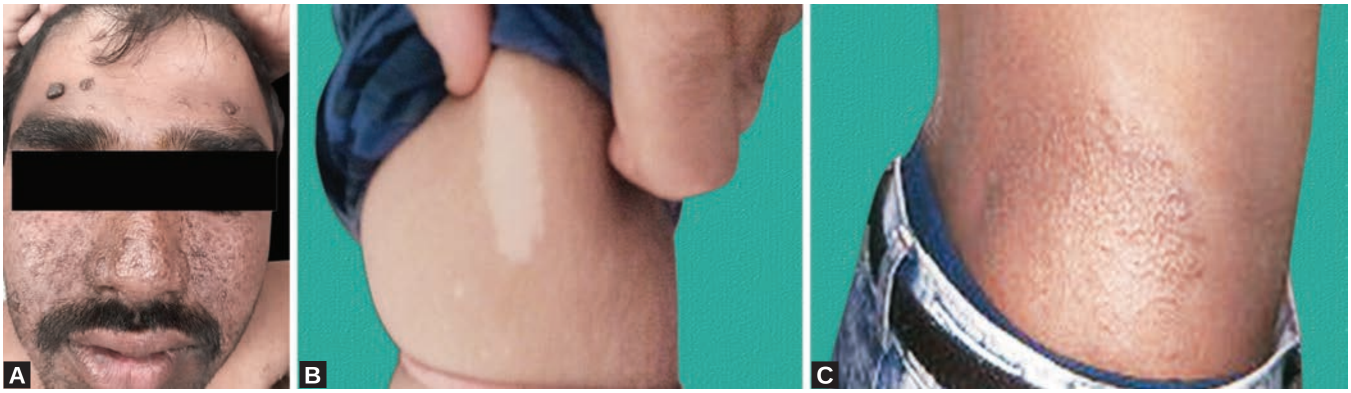
- Tuberous sclerosis complex is an inherited neurocutaneous disorder characterized by pleomorphic features involving many organ systems, including multiple benign hamartomas of the brain, eyes, heart, lung, liver, kidney, and skin.
- It is called as **Bourneville disease**, as it was first described by him in 1880.
- Clinical triad of Vogt—**EPI-LOI-A:** Epilepsy, low intelligence, and adenoma sebaceum (**Fig. 19.23A**).
- Incidence—1 in 6,000–9,000
- Dominant inheritance but a high frequency of spontaneous mutation.

Diagnostic criteria for tuberous sclerosis complex are given in **Table 19.9**.

TABLE 19.9: Diagnostic criteria for tuberous sclerosis complex (TSC).

Major features	*Minor features*
Facial angiofibromas or forehead plaque	Multiple randomly distributed pits in dental enamel
Nontraumatic ungual or periungual fibroma	Hamartomatous rectal polyps
Hypomelanotic macules (more than three) (**Fig. 19.23B**)	Bone cysts
Shagreen patch (connective tissue nevus) (**Fig. 19.23C**)	Cerebral white matter migration lines
Multiple retinal nodular hamartomas	Gingival fibromas
Cortical tuber	Non-renal hamartoma
Subependymal nodule	Retinal achromic patch
Subependymal giant cell astrocytoma	"Confetti" skin lesions
Cardiac rhabdomyoma—single or multiple	Multiple renal cysts
Lymphangiomyomatosis	
Renal angiomyolipoma	

Definite TSC: Either two major features or one major feature with two minor features
Probable TSC: One major feature and one minor feature
Possible TSC: Either one major feature or two or more minor features



FIGS. 19.23A TO C: (A) Adenoma sebaceum; (B) Ash leaf-shaped macule is a hypopigmented macule oval at one end and pointed at the opposite end; (C) Shagreen patches.

Café-au-lait Macules

Q. Write short note on café-au-lait macules (CALMs).

- These are well-circumscribed, evenly pigmented macules (**Fig. 19.24**); size ranges from 1 to 2 mm to >20 cm.
- Microscopically shows increased melanin in both melanocytes and basal keratinocytes.
- In McCune–Albright syndrome, CALM may have a block-like distribution with midline demarcation and an irregular, jagged outline ("coast of Maine").
- In NF1, there is more numbers of CALM and has more widespread distribution (with the exception of segmental NF1), which is "typical" based on their regular borders, smooth ("coast of California") and uniform pigmentation. In adults, the presence of six or more café-au-lait macules is highly suggestive of NF1.
- In fair-skinned infants, they may be difficult to detect on routine physical examination, but are accentuated with examination under a Wood's lamp.
- CALMs may be observed in tuberous sclerosis, ataxia telangiectasia, Bloom's syndrome, and Watson's syndrome.

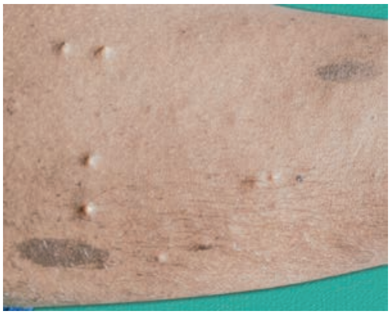


FIG. 19.24: Café-au-lait macules (CALMs).

DISORDERS OF SKIN APPENDAGES

Acne Vulgaris

Q. DR1.1 Enumerate the causative and risk factors of acne.

Q. DR1.2 Identify and grade the various common types of acne.

Q. DR1.3 Describe the treatment and preventive measures for various kinds of acne.

- Acne is a multifactorial disease characterized by abnormalities in sebum production, follicular desquamation, bacterial proliferation, and inflammation.
- **Age and gender:** It starts after puberty and is seen primarily in teenagers (12–20 years of age) and young adults. 85% adolescents experience it. Prevalence of comedones in adolescents approaches 100%. But, it can persist into the thirties and forties, particularly in females. It affects both males and females, although males tend to have more severe disease.

Cutibacterium acnes, Staphylococcus epidermis, and *Malassezia furfur* induce inflammation and induce follicular epidermal proliferation.

Clinical Features (Table 19.10)

- **Sites:** Most common location for acne is the face (**Fig. 19.25**), but it may involve the chest and back (trunk).
- Greasiness of the skin (seborrhea) is often observed.
- **Type of lesions:** The hallmark is the **comedone.**

TABLE 19.10: Factors that induce or exacerbate acne vulgaris (secondary acne).

- **Endocrine causes:** Polycystic ovary syndrome, Cushing's syndrome, congenital adrenal hyperplasia, androgen-secreting tumors of adrenals, ovary and testis, and acromegaly
- **Drugs:**
  - **Glucocorticoids:** Systemic and local agents
  - **Hormones:** Adrenocorticotropic hormone, testosterone, gonadotropins, and oral contraceptives
  - **Halides:** Iodides and bromides
  - **Anabolic:** Danazol and stanozolol
  - **Anticonvulsants/antiepileptics:** Phenytoin, carbamazepine, topiramate, gabapentin, and lithium
  - **Antidepressants:** Amitriptyline, lithium, and sertraline
  - **Antituberculous:** Isoniazid and rifampicin
  - **Chemotherapeutic agents:** Dactinomycin, pentostatin, and gefitinib
  - **Antineoplastic drugs:** Epidermal growth factor receptor (EGFR) inhibitor, and cetuximab
  - **Antiviral:** Ritonavir and ganciclovir
  - **Vitamins:** B_6 and B_{12}
- **Occupational exposures:** To cutting oils, chlorinated aromatic hydrocarbons, and coal tars
- **Conditions favoring occlusion of sebaceous glands**, e.g., heavy clothing, greasy cosmetics, and tropical climates
- **Genetic factors**

Microcomedone

- *Hyperkeratotic plug made of sebum and keratin in follicular canal*
- These comedones may be noninflammatory or inflammatory type (open or closed comedones)
- Open comedones (blackheads) appear as black papules due to the keratin debris and closed comedones (white heads) usually have no visible follicular opening. Inflammatory papules, nodules, and cysts may arise from comedones.

Sequelae: Most cases remain mild and do not lead to scarring. Few may develop large inflammatory cysts and nodules and may heal by significant scarring. Solid facial edema

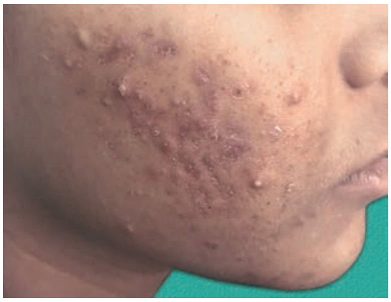

FIG. 19.25: Acne vulgaris.

(Morbihan's disease) is a rare complication of acne that presents as facial soft-tissue edema and erythema. Postinflammatory hyperpigmentation and bacterial folliculitis can be seen.

Grading of acne

- *Grade 1*: Comedones. They are of two types—open and closed. Open comedones are due to plugging of the pilosebaceous orifice by sebum on the skin surface. Closed comedones are due to keratin and sebum plugging the pilosebaceous orifice below the skin surface.
- *Grade 2*: Inflammatory lesions present as a small papule with erythema.
- *Grade 3*: Pustules
- *Grade 4*: Many pustules coalesce to form nodules and cysts

Clinical variants

- **Acne conglobata** is rare and commonly affects adult males. It is a severe form of acne characterized by numerous comedones, large abscesses with sinuses, grouped inflammatory nodules associated with suppuration. It may be associated with **hidradenitis suppurativa** (a chronic, inflammatory disorder of apocrine glands, mainly affecting axillae and groins), folliculitis, and pilonidal sinus.
- **Acne fulminans** is a rare, severe variant of acne, usually affecting the trunk in adolescent males. It presents with fever, arthralgias, and systemic inflammation, with leukocytosis and raised plasma viscosity.
- **Acne excoriée** (also known as "picker's acne") is self-inflicted excoriations produced by compulsive picking of pre-existing or imagined acne lesions. It is usually observed in teenage girls with psychological problems.
- **SAPHO syndrome:** Synovitis, Acne, Pustulosis, Hyperostosis, and Osteitis syndrome.
- **Acne venenata:** Contact with acnegenic chemicals can produce comedones. For example, chlorinated hydrocarbons, cutting oils, petroleum oil, and coal tar.
- **Acne aestivalis** (Mallorca acne): It is rare and seen in females 25–40 years. It starts in spring and resolves by fall characterized by small papules on cheeks, neck, and upper body. Comedones and pustules are sparse or absent.

Management

Mild-to-moderate disease

Local therapy:

- Areas affected with acne should be kept clean by regular washing with soap and water. However, vigorous scrubbing may cause mechanical rupture of comedones.
- Topical agents such as benzoyl peroxide (most cost-effective therapy), retinoids [tretinoin (most potent keratolytic agent), adapalene (less irritating), or tazarotene], or salicylic acid should be used.
- *Topical antibacterial agents*: Inflammatory acne responds to topical antibacterial agents such as azelaic acid, topical erythromycin, or clindamycin.
- Topical Dapsone

Systemic therapy:

- *Antibiotics*: Moderate inflammatory acne will benefit from the addition of systemic therapy such as oral tetracycline (oxytetracycline or lymecycline), doxycycline (200 mg/day), or minocycline (200 mg/day) for 3–6 months.
- *Hormonal therapy*: These include estrogen-containing oral contraceptives or a combined estrogen/anti-androgen (such as cyproterone acetate) contraceptive.

Moderate-to-severe disease

- **Isotretinoin:** Moderate-to-severe acne or if there is no adequate response to 6 months of therapy with the other therapies (combined systemic and topical approaches), patients should be considered for isotretinoin (13-*cis*-retinoic acid).
  - **Mechanism of action:** It decreases sebaceous gland size and sebum excretion, decreases follicular hypercornification and reduces *P. acnes* colonization.
  - **Side effects:** Oral isotretinoin is teratogenic (prevent pregnancy while taking isotretinoin), and possibly associated risk for severe depression, pseudotumor cerebri and other significant side effects.

Other treatments and physical measures:

- **For inflamed acne nodules or cysts:** They may require intralesional injections of **triamcinolone acetonide or** incision and drainage, **or** excision under local anesthesia.
- **Scarring:** Prevention of scarring by adequate treatment of active acne. Keloid scars respond to intralesional steroid injection and/or silicone dressings. Other measures for scarring include carbon dioxide laser, microdermabrasion, chemical peeling, or localized excision.
- **UVB phototherapy:** They are rarely used in patients with inflammatory acne who are unable to use conventional therapy, such as isotretinoin.

HAIR DISORDERS

Q. List the causes of alopecia.

Alopecia: Alopecia is defined as “absence or loss of hair”. It is a chronic disorder secondary to the disease of either the hair follicle, hair shaft, or the scalp.

Alopecia

Classification and Causes of Alopecia (Table 19.11)

TABLE 19.11: Classification and causes of alopecia.

Localized	*Diffuse*
Nonscarring	
A. **Abnormality of cycling:** – Alopecia areata – Syphilitic alopecia B. **Production decline:** – Androgenetic alopecia – Triangular alopecia C. **Hair breakage:** – Trichotillomania – Tinea capitis – Traction alopecia – Primary or acquired hair shaft abnormality	A. **Abnormality of cycling:** – Alopecia areata – Telogen effluvium – Anagen effluvium – Loose anagen syndrome B. **Hair shaft abnormality:** – Hair breakage – Unruly hair C. **Failure of follicle production:** – Congenital universal atrichia – Atrichia with papular lesions – Hereditary vitamin-D-resistant rickets
Androgenetic, hypothyroidism, hyperthyroidism, hypopituitarism, diabetes mellitus, HIV, nutritional (especially iron) deficiency, liver disease, postpartum, alopecia areata, syphilis, drug-induced (e.g., chemotherapy and retinoids)	
Scarring	
A. **Lymphocytic:** – Chronic cutaneous lupus erythematosus, discoid lupus erythematosus (DLE) – Lichen planopilaris – Classic pseudopelade of Brocq – Alopecia mucinosa B. **Neutrophilic:** – Folliculitis decalvans – Dissecting folliculitis/cellulitis C. **Mixed:** – Folliculitis (acne) keloidalis – Folliculitis (acne) necrotica – Erosive pustular dermatitis	➢ Discoid lupus erythematosus ➢ Radiotherapy ➢ Folliculitis decalvans ➢ Lichen planus

Alopecia Areata

Definition: Rapid and complete loss of hair in one or most often several round or oval patches, usually on the scalp (**Fig. 19.26**), bearded area, eyebrows, eye lashes, and less commonly on other hairy areas of the body.

Approximately 1.7% of the population will experience an episode of alopecia areata during their lifetime.

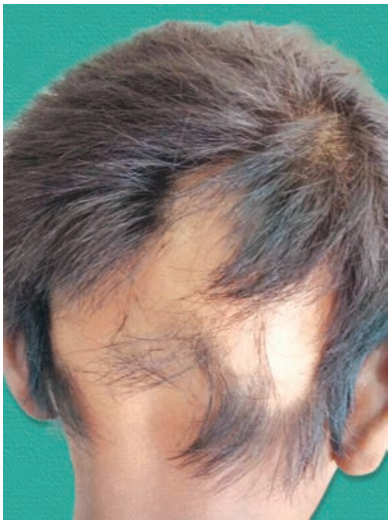

FIG. 19.26: Alopecia areata.

Etiology

It is an autoimmune disease:

- Mediated by the cellular arm (T-cell and macrophages)
- Modified by genetic factors (HLA-R4, DR11, and DQ7)

Stages of alopecia areata (Box 19.20)

Box 19.20: Stages of alopecia areata.

- Acute hair loss
- Persistent (chronic) baldness
- Partial telogen to anagen conversion (incomplete recovery)
- Normal recovery

Clinical features

- Rapid and complete loss of hair in one or several patches (**Fig. 19.26**)
- *Site*: Scalp, bearded area, eyebrows, eyelashes, and less commonly other areas of body
- *Size*: Patches of 1–5 cm in diameter
- **Exclamation point hairs,** short broken hairs for which the proximal end of the hair is narrower than the distal end, are pathognomonic finding in alopecia areata.

Alopecia totalis is a more advanced form of alopecia areata, which results in total loss of all hair on the scalp.

Alopecia universalis is the most advanced form of alopecia areata, which results in total loss of all hair on the body, including eyelashes and eyebrows.

Alopecia barbae is alopecia areata that is localized to the beard area. It can be a single bald patch or more extensive hair loss across the whole of the beard area.

Androgenetic Alopecia (Fig. 19.27)

- It is a thinning of the hair to an almost transparent state in both men and women.
- It is hereditary.
- In both men and women, it is linked to having an excess of male hormones (androgens) around the hair follicles, which can block hair growth.
- Women are more likely to develop androgenic alopecia after menopause, when they have fewer female hormones.

Investigations

- *Blood investigations*: Complete blood count, serum ferritin, blood sugar, renal and liver function, hormones (thyroid, FSH, LH, and testosterone), vitamin B_{12}, and vitamin D
- *Trichometric analysis*: The folliscope can magnify these images by up to 100 times, giving doctors a detailed look at hair, hair follicles, and the scalp
- Fungal culture
- Punch biopsy—used to distinguish between the types of cicatricial, or scarring, alopecia.
- *Daily hair counts*:
  - Useful for quantitative assessment of the actual number of hairs shed daily in patients with complaints of excessive shedding. Collect for 14 consecutive days
  - Average daily loss—30–70 hairs/day
  - If >70 hairs—microscopic examination is done to detect pathology

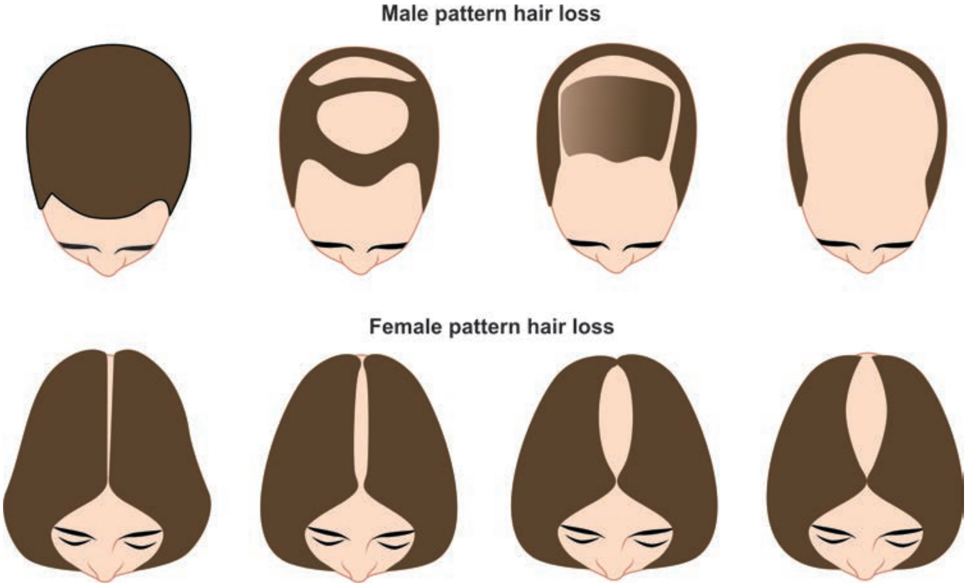

FIG. 19.27: Male and female pattern of hair loss.

Treatment

- Many cases of hair loss are temporary, for example, due to chemotherapy, or they are a natural part of aging and do not need treatment.
- If hair loss is caused by an infection or another condition, treating the underlying problem may help to prevent further hair loss
- Spontaneous recovery is extremely common for patchy alopecia areata.
- *Steroid*: Both local (intralesional and topical) and systemic (in short course)
- *Topical 1% anthralin cream*: Applied for 15–20 minutes and then shampooed off the treated side
- *5% topical minoxidil*: As a single agent or as an adjuvant with topical anthralin
- PUVA
- *Contact sensitizer*: Squaric acid dibutylester, diphencyprone, and dinitrochlorobenzene
- *Finasteride*: It acts by preventing the hormone testosterone being converted to the hormone dihydrotestosterone (DHT). DHT causes the hair follicles to shrink, so blocking its production allows the hair follicles to regain their normal size.
- Psychological support
- Hair transplantation is a surgical technique that removes hair follicles from one part of the body, called the "donor site", to a bald or balding part of the body known as the "recipient site". The technique is primarily used to treat male pattern baldness.
- Follicular unit transplantation (FUT) is a hair restoration technique, also known as the strip procedure, where a patient's hair is transplanted in naturally occurring groups of 1–4 hairs, called follicular units.

LEG ULCERS

Q. Write short note on causes of nonhealing leg ulcer.

Ulceration of the skin is defined as complete epidermal loss. It results in exposure of dermal (or deeper) layers.

Causes of Leg Ulcers (Table 19.12 and Fig. 19.28)

TABLE 19.12: Causes of leg ulcer.

Venous hypertension: Deep vein thrombosis **Arterial disease:** ➢ Atherosclerosis ➢ Vasculitis ➢ Buerger's disease **Small-vessel disease:** ➢ Diabetes mellitus ➢ Vasculitis **Malignant skin tumors:** ➢ Squamous cell carcinoma ➢ Basal cell carcinoma ➢ Malignant melanoma ➢ Kaposi's sarcoma	**Blood disorders:** ➢ Sickle cell anemia ➢ Cryoglobulinemia ➢ Spherocytosis ➢ Hyperviscosity states, e.g., polycythemia ➢ Immune complex disease **Neuropathy:** ➢ Diabetes mellitus ➢ Leprosy (Hansen's disease) ➢ Syphilis **Trauma:** ➢ Injury ➢ Artifact

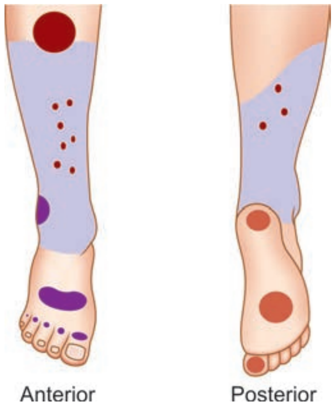

FIG. 19.28: Causes of leg ulcers.

XEROSTOMIA

Q. Write short note on xerostomia.

- Normal healthy adults daily produce about 1,500 mL of saliva.
- Xerostomia is characterized by dry mouth and may be due to decrease in the production of saliva.

Management

- Stop the offending drug
- Frequent sips of water and teeth brushing
- **Oral hygiene:** Chlorhexidine rinses
- **Artificial salivary substitutes:** They act as lubricant and protective and not as substitutes for digestive and enzymatic actions (e.g., sodium carboxymethyl cellulose, potassium dihydrogen orthophosphate, and sorbitol).
- **Cholinergic agonists:** *Pilocarpine and cevimeline*: It should be cautiously used in patients with cardiovascular disease and chronic respiratory conditions. They are contraindicated in patients with uncontrolled asthma, angle-closure (narrow angle) glaucoma, and liver disease.

Effects of Xerostomia

- Symptoms may be minor or may hamper activities of daily living.
- May produce burning sensation in mouth, difficulty in eating, chewing, and swallowing
- May produce tooth decay, bad breath, candida infection, and viral infections (e.g., herpes simplex)

Etiology

- **Anticholinergic drugs** (reduce volume of saliva): For example, anticholinergics, antidepressants, antipsychotics, antiemetics, antihistamines, antihypertensives, antiparkinsonian drugs, antispasmodics, and diuretics.
- **Sympathomimetic drugs** (produce viscous saliva): For example, amphetamines, appetite suppressants, decongestants, and bronchodilators
- **Systemic diseases:** Addison's disease, Alzheimer's diseases, salivary gland infection, Sjögren's syndrome, alcoholic cirrhosis, diabetes mellitus, HIV/AIDS, radiation to head and neck region (e.g., for cancer therapy), and severe dehydration.
- **Other causes:** Elderly individuals, sleep-related xerostomia (due to mouth breathing during sleep).

PRURITUS

Q. Write short essay/note on pruritus/generalized pruritus and its causes.

The terms "itch" and "pruritus" are used synonymously; however, "pruritus" is often used for generalized itch.

Definition: Itch is an unpleasant cutaneous sensation that leads to scratching or rubbing.

Causes (Box 19.21 and Table 19.13)

Box 19.21: Dermatological causes of pruritus.

- Atopic dermatitis
- Scabies
- Xerosis
- Lichen simplex chronicus
- Contact dermatitis
- Insect bites
- Sunburn
- Ichthyoses
- Dermatitis herpetiformis
- Psoriasis
- Lichen planus
- Fungal infections
- Pediculosis
- Plaster of Paris casts

TABLE 19.13: Systemic causes of pruritus.

Autoimmune: ➢ Dermatitis herpetiformis ➢ Dermatomyositis	**Hepatobiliary:** ➢ Biliary cirrhosis ➢ Drug-induced cholestasis
Hematological: ➢ Hemochromatosis ➢ Mastocytosis ➢ Polycythemia vera	**Metabolic and endocrine:** ➢ Carcinoid syndrome ➢ Chronic renal disease ➢ Diabetes mellitus
Infectious diseases: ➢ AIDS ➢ Infectious hepatitis ➢ Parasitic diseases (e.g., giardiasis and ascariasis)	**Malignancy:** ➢ Leukemia and lymphoma ➢ Multiple myeloma ➢ Solid tumors with paraneoplastic syndrome
Neurologic: ➢ Cerebral abscess ➢ Cerebral tumor	**Others:** ➢ Drug ➢ Pregnancy

Management/Treatment

General measures:

- Avoid soap
- Control of xerosis with moisturizers and humidification of indoor environment

Specific measures:

- Establish the diagnosis and treat the underlying skin or systemic disease
- If a clear-cut diagnosis is not possible, various nonspecific measures can be used for symptom control. It is necessary to reassess intermittently in order to avoid missing the diagnosis.
- UVB (ultraviolet B) phototherapy in chronic kidney disease
- Ursodeoxycholic acid (UDCA) in cholestasis
- Cholestyramine, rifampicin, and opioid antagonists (e.g., naltrexone) in primary biliary cirrhosis
- Corticosteroids in Hodgkin's disease
- Paroxetine (selective serotonin reuptake inhibitor) in itching as paraneoplastic manifestation of malignancies

Symptomatic measures:
- These include sedation, often with H_1 antagonist antihistamines, emollients, and counter irritants (such as topical menthol-containing preparations).
- *Intractable cases*: Phototherapy, low-dose tricyclic antidepressants (e.g., amitriptyline), or gabapentin may help.

Complications of pruritus:
- Prurigo nodularis is a variant of lichen simplex chronicus in which nodules develop at the site of scratching.
- Local infection due to scratching
- Lichen simplex chronicus is localized skin thickening produced due to intense scratching.

PANNICULITIS

- Panniculitis is an inflammatory reaction in the subcutaneous fat tissue.
- Panniculitis may preferentially affect—(1) the lobules of fat (lobular panniculitis with necrosis and purpura) or (2) the connective tissue that separates fat into lobules (septal panniculitis).

Erythema Nodosum

Q. Write short essay/note on the etiology, clinical features, diagnosis, and treatment of erythema nodosum.

- Erythema nodosum (septal panniculitis) is the most common form of panniculitis.
- It is also called subacute migratory panniculitis of Vilanova and Piñol.

Etiology

Factors provoking erythema nodosum: Occurrence of erythema nodosum is often associated with provoking factors (**Box 19.22**). Most often, it is idiopathic without any identifiable underlying cause.

Box 19.22: Triggering factors associated with erythema nodosum.

Infections:
- Bacteria, e.g., **β-hemolytic streptococci,** mycobacteria (usually primary **tuberculosis,** leprosy), *Brucella, Mycoplasma, Rickettsia, Chlamydia, Salmonella,* and *Yersinia*
- Viruses, e.g., hepatitis B and infectious mononucleosis
- Fungi, e.g., coccidioidomycosis, histoplasmosis, and blastomycosis
- Parasitic, e.g., amebiasis and giardiasis
- *Drug administration*, e.g., **sulfonamides,** sulfonylureas, and oral contraceptives
- *Systemic disease*, e.g., **sarcoidosis,** inflammatory bowel disease, and Behcet's disease

Malignancies: Lymphoma, leukemia, and renal cell carcinoma.

Idiopathic: >50% cases

Clinical Features

Age and gender: Age 20–30 years but any age group may be affected. Female-to-male ratio is 3–6:1.

*Lesions (**Table 19.14 and Fig. 19.29**)*

TABLE 19.14: Features of lesions erythema nodosum.

➢ Sudden onset ➢ Symmetrical ➢ Painful ➢ Erythematous ➢ Warm ➢ Nonulcerated nodules/plaques ➢ Knees, shins, and feet may be at thighs, arms, and face	➢ Undergo color changes as advance in the duration ➢ Resolve without scarring or atrophy ➢ Associated with pyrexia, malaise, headache, and arthralgias ➢ Recurrent episodes are known

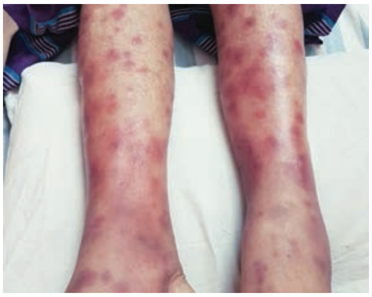

FIG. 19.29: Erythema nodosum on both legs.

Diagnosis

- Most often based on clinical presentation
- **Deep wedge biopsy** including the subcutis is usually required for histologic diagnosis. Histologically shows inflammation of the connective tissue septa in the subcutaneous fat tissue (septal panniculitis). Vasculitis is not observed.
- **Dentification of triggering factors causing erythema nodosum:**
  - Complete blood count (CBC) with differential ESR (erythrocyte sedimentation rate) and C-reactive protein level
  - *Evaluation for β-hemolytic streptococcal infection*: Throat culture for group A streptococci, rapid antigen test, anti-streptolysin-O titer, and polymerase chain reaction assay
  - Chest radiograph, e.g., to detect tuberculosis and sarcoidosis—Mantoux test
  - Stool examination for ova and parasite, e.g., in patients with GIT symptoms
  - Evaluation for inflammatory bowel disease in patient with symptoms of IBD

Treatment

- Identify and remove/treat any underlying cause (treatment of tuberculosis/IBD/sarcoid).
- Bed rest, leg elevation, and analgesics with NSAIDs may produce symptomatic relief. However, avoid NSAIDs, if secondary to Crohn disease because they may trigger a flare-up the underlying Crohn disease.
- Systemic corticosteroids must be avoided in cases with infection and malignancy.
- Dapsone and potassium iodide orally (400–900 mg/day) have been effective for stubborn disease (if NSAIDs do not relieve pain or the lesions persist) for symptomatic relief. Recalcitrant, chronic, or recurring EN is treated with thalidomide, colchicine, and hydroxychloroquine.

LEPROSY

Q. DR9.1 **Classify and describe the epidemiology, etiology, microbiology, pathogenesis, clinical presentations and diagnostic features of leprosy.**

Definition: Leprosy (Hansen's disease) is a **chronic, granulomatous,** slowly progressive, destructive infection affecting skin and nerves, caused by *Mycobacterium leprae.*

Epidemiology

- The WHO launched a 5-year "Global Leprosy Strategy 2016–2020" in April, 2016 titled "accelerating towards a leprosy-free world".
- In India, the National Leprosy Eradication Programme (NLEP) is the centrally sponsored health scheme of the Ministry of Health and Family Welfare, Government of India.
- India continues to account for 60% of new cases reported globally each year and is among the 22 "global priority countries" that contribute 95% of world numbers of leprosy warranting a sustained effort to bring the numbers down.
    - **Mode of transmission:** (1) Inoculation/inhalation and (2) Intimate contact
    - **Incubation period:** Generally 2–7 years

Bacteriological Considerations

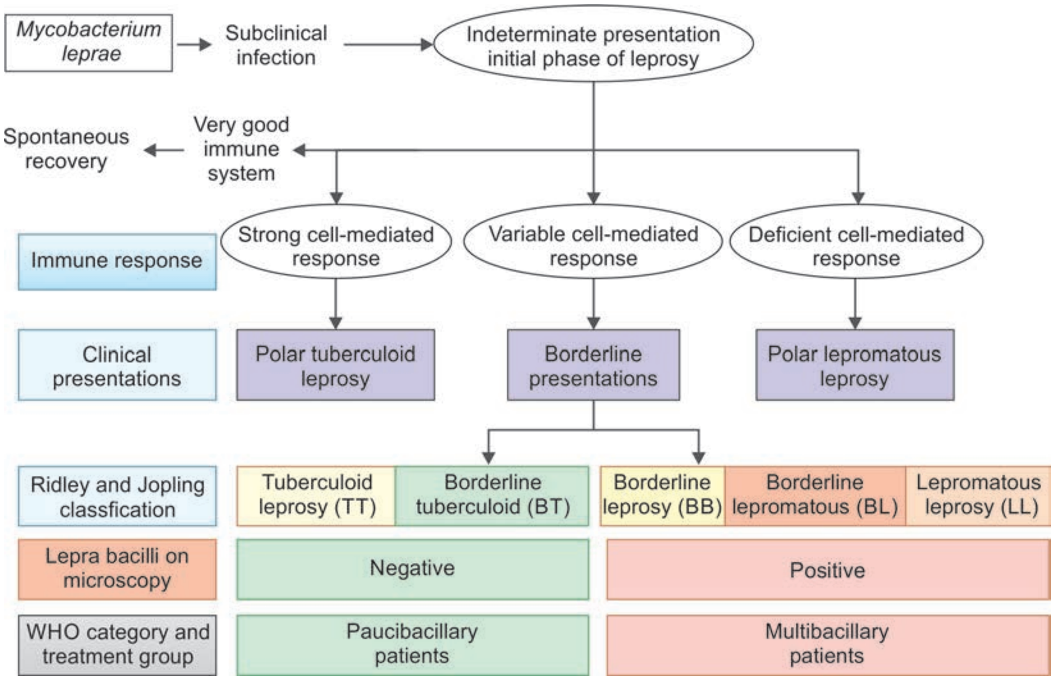
- *Mycobacterium leprae* is an acid and alcohol fast, intracellular bacillus.
- Lepra bacilli survive and grow better at a temperature below that of the internal organs (close to 30°C rather than 37°C). Hence, it affects sites such as skin, peripheral nerves, the mucosa of the upper airways, and other tissues (bone, eyes, testis, and some viscera).
- *Mycobacterium leprae* can be grown in the footpads of mice and **nine-banded armadillos. Cannot be cultured** on artificial media or in cell culture.

Classification (Fig. 19.30)

In the early stage, disease may be indeterminate and may either spontaneously undergo remission or develop into overt leprosy.

A. **Ridley and Jopling (1966) classification:** It depends on the clinicopathological spectrum of the disease, which is **determined by the immune resistance of the host**.
    - **Tuberculoid leprosy (TT):** It is the polar form that has maximal immune response. It is characterized by single or few sharply demarcated skin lesions with predominant peripheral nerve involvement. The bacilli are usually absent or difficult to demonstrate.
    - **Borderline tuberculoid (BT):** In this type, the immune response falls between BB and TT.
    - **Borderline leprosy (BB):** It exactly falls between two polar forms of leprosy.
    - **Borderline lepromatous (BL)** has the immune response that falls between BB and LL.
    - **Lepromatous leprosy (LL):** It is the other polar form with least immune response. This is characterized by extensive, diffuse, and bilaterally symmetrical skin lesions that contain numerous bacilli. The peripheral nerves are better preserved than in the tuberculoid form.
    - **Indeterminate type:** When the biopsy sample shows definite diagnostic evidence of leprosy (both nerve involvement and acid-fast bacilli) but clinically not fitting to the leprosy spectrum.

B. **WHO classification:**
    - *Paucibacillary*: All cases of tuberculoid leprosy and some cases of borderline type
    - *Multibacillary*: All cases of lepromatous leprosy and some cases of borderline type bacilli are present in large numbers, and hence the term multibacillary (MB).



Mycobacterium leprae
Subclinical infection
Indeterminate presentation initial phase of leprosy
Spontaneous recovery
Very good immune system
Immune response
Strong cell-mediated response
Variable cell-mediated response
Deficient cell-mediated response
Clinical presentations
Polar tuberculoid leprosy
Borderline presentations
Polar lepromatous leprosy

Multibacillary patients

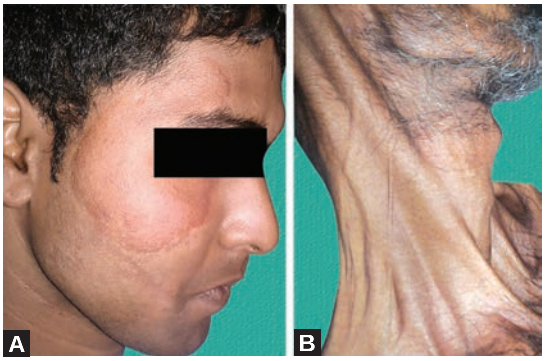
FIG. 19.30: Classification of leprosy.

Clinical Features

Tuberculoid Leprosy

Q. DR9.2 Discuss the clinical features of tuberculoid leprosy.

- **Skin lesions:** The early features consist of one or few, localized, well-demarcated, dry, elevated, **hypoesthetic, red or hypopigmented** macules (**Fig. 19.31A**). Later, the lesions become larger, margins elevated and circinate or gyrate. Fully developed lesions are anesthetic and show loss of sweat glands and hair follicles.
- **Nerve involvement** occurs early and is **the dominating feature** in tuberculoid leprosy. It is usually asymmetric and the involved nerves (**Fig. 19.31B**) are thickened and palpable. Routinely, the nerves such as ulnar, peroneal (lateral popliteal), and greater auricular nerves should be palpated. Sometimes, TT may present with only nerve involvement without any skin lesions **(neural leprosy or pure neuritic leprosy)**. Consequences (complications) of nerve involvement are:
  - **Sensory nerve involvement** produces sensory dysfunctions such as glove and stocking anesthesia (more common in LL), chronic nonhealing, plantar ulcers, and repeated injuries to hands and feet (leading to **autoamputation** of fingers or toes).
  - **Motor nerve involvement** produces muscle weakness, wasting, and later paralysis followed by contractures. Nerves involved and their consequences are as follows:
    - **Ulnar nerve:** Claw hand (main en griffe) (**Fig. 19.32**)
    - **Median nerve:** Ape hand (main de singe)
    - **Lateral popliteal nerve:** Foot drop
    - **Posterior tibial nerve:** Claw toes or hammer toes
  - **Autonomic involvement** produces anhidrosis or hyperhidrosis
  - **Cranial nerve involvement:** Facial nerve is commonly affected and results in facial paralysis, lagophthalmos, exposure keratitis,



FIGS. 19.31A AND B: Lesions of tuberculoid leprosy: (A) Hypopigmented macules on face; (B) Visible greater auricular nerve thickening.

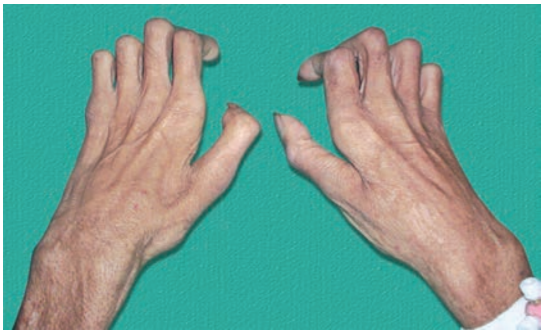


FIG. 19.32: Bilateral claw hand.

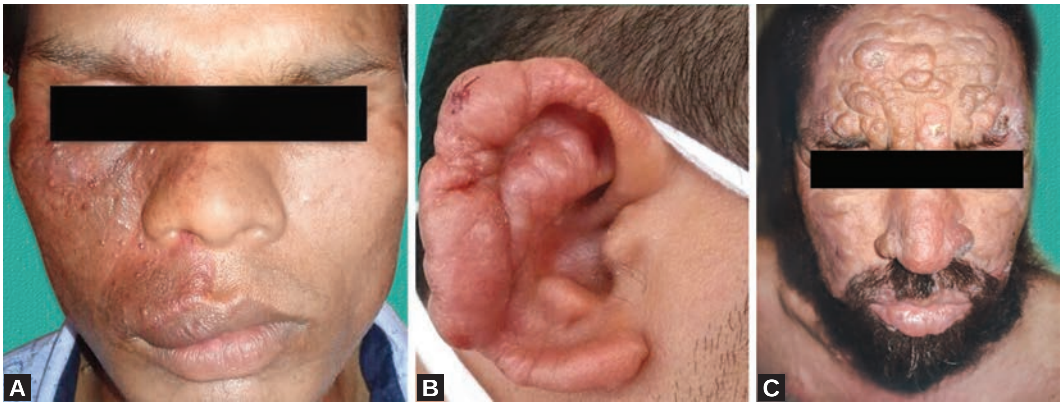
and corneal ulcerations (may lead to blindness). Trigeminal nerve involvement may develop early causing loss of corneal reflex. Greater auricular nerve (**Fig. 19.31B**), supraorbital, supratrochlear, and infraorbital nerves are also thickened.

Lepromatous Leprosy

Q. DR9.2 **Discuss the clinical features of multibacillary/lepromatous leprosy.**

- **Nasal symptoms** are the early features of LL and include anosmia, nasal stuffiness, crust formation, and blood-stained nasal discharge.
- **Skin lesions** include **multiple, symmetric, macules, papules,** plaques, **or nodules**. The macules are often hypopigmented. The borders of the lesions are ill-defined, centers indurated, raised, and convex ("inverted saucer" appearance). There is also diffuse infiltration between the lesions. The nodular skin lesions may ulcerate. The lesions are more common on the face (cheeks, nose, and eyebrows) (**Fig. 19.33A**), ears, wrists, elbows, buttocks, and knees. With progression, the nodular lesions in the face and ear lobes (**Fig. 19.33B**) may coalesce to produce thickening of face and corrugated forehead. This produces a lion-like appearance known as **leonine facies** (**Fig. 19.33C**). This may be accompanied by loss of eyebrows and eyelashes.



FIGS. 19.33A TO C: Lesions of lepromatous leprosy: (A) Facial involvement; (B) Nodular lesions on ear; (C) Leonine facies.

- **Nerve involvement** of major nerve trunks is less prominent in LL. In advanced disease, **loss of sensation with** "glove and stocking" anesthesia is common. Mononeuritis multiplex can also occur.
- Lepromatous leprosy without visible skin lesions but with diffuse dermal infiltration and a demonstrable thickening of dermis is called *diffuse lepromatosis*.
- **Bone involvement:** It may develop in hands, feet (phalanges, metatarsals, and tarsal bones), and skull. It causes slow absorption of distal phalanges resulting in shortening of fingers. In the skull, it may produce atrophy of the anterior nasal spine (leading to nasal collapse) and atrophy of maxillary alveolar process (causing loosening and loss of upper incisors). These changes in the skull produce "facies leprosa".
- **Other features:**
  - **Bilateral edema** of legs and ankles
  - **Saddle nose:** Swollen and broad nose, septal perforation, and nasal collapses produce saddle nose deformity.
  - **Teeth:** Loosening of upper incisor teeth, which may later fall off
  - **Anterior chamber of the eye** involvement results in keratitis, iridocyclitis, and **blindness.**
  - **Upper airways:** Chronic nasal discharge, laryngitis, palatal perforation, and hoarseness (voice change).
  - **Testes:** Usually severely involved, leading to destruction of the seminiferous tubules, testicular atrophy, impotence, infertility, and gynecomastia.
  - **Painless lymphadenopathy** involving inguinal and axillary lymph nodes
  - **Renal lesions:** Secondary glomerulonephritis, interstitial nephritis, pyelonephritis, and renal amyloidosis

Q. DR9.7 **Enumerate and describe the complications of leprosy and its management.**

Complications of lepromatous leprosy are summarized in **Box 19.23**.

Borderline Leprosy

Clinical features are poorly defined and these overlap with features of other subtypes.

Box 19.23: Complications of lepromatous leprosy.

- **Permanent nerve damage with sensory loss** (usually begins in extremities):
  - Leading to skin ulcers
  - "Glove and stocking"anesthesia
  - Mononeuritis multiplex
- **Infection of skin ulcers**
- **Disfiguration of the face** (leonine facies)
- **Eye damage:** Keratitis, iridocyclitis, and blindness
- **Upper airways:**
  - *Nasal damage*: Anosmia, nasal stuffiness, crust formation, and blood-stained nasal discharge
  - Laryngitis, palatal perforation, and hoarseness (voice change)
- **Muscle weakness:** Claw-like hands or an inability to flex the feet
- **Bone involvement:**
  - *Hands and feet*: Slow absorption of distal phalanges (shortening of fingers)
  - *Skull*: Nasal collapse and atrophy of maxillary alveolar process, saddle nose
- **Testes:** Testicular atrophy, impotence, infertility, and gynecomastia
- **Renal lesions:** Secondary glomerulonephritis, interstitial nephritis, pyelonephritis, and renal amyloidosis

Reactions in Leprosy or Lepra Reactions

Immunity in leprosy may change spontaneously or following treatment. The course of leprosy may be interrupted by lepra reactions, which comprise several common immunologically mediated inflammatory states. There are two types of lepra reactions. Both types of reactions can occur in untreated patients, but more often develop as complications of chemotherapy.

Type I Lepra Reaction

Q. DR9.4 Enumerate, describe and identify lepra reactions and supportive measures and therapy of lepra reactions.

Borderline leprosy (BT, BB, or BL) is the **most unstable form of leprosy** where **immune status may shift up or down and** type I reaction occurs in 50% of these patients. These are delayed hypersensitivity reactions and may be of two types: **Downgrading reaction and reversal reaction.**

1. **Downgrading reaction:** If type I lepra reactions precede the initiation of appropriate antimicrobial therapy, they are termed as downgrading reactions. It is associated with decrease of immunity and histologically the disease moves (usually from borderline) toward lepromatous leprosy.
2. **Upgrading/reversal reaction:** If type I lepra reactions occur after the initiation of antimicrobial therapy, they are termed as reversal reactions. It is associated with improved immunity and histologically the disease moves (usually from borderline) toward tuberculoid leprosy. It develops usually in the 1st month or year after the initiation of therapy but may also occur after several years.

Manifestations: Existing skin lesions (i.e., macules, papules, and plaques) develop classic signs of inflammation in the form of erythema and swelling and new skin lesions may appear. Peripheral nerves inflammation (i.e., neuritis) causes pain and exquisitely tenderness of nerves. Irreversible nerve damage may occur suddenly (24 hours) unless the reaction is treated promptly.

Type 2 Lepra Reaction or Erythema Nodosum Leprosum

It occurs mostly in lepromatous leprosy (BL/LL) particularly within 2 years of institution of chemotherapy. It develops due to widespread immune-complex deposition (type III hypersensitivity reactions) and overproduction of tumor necrosis factor (TNF-α).

Manifestations

- **Crops** of painful, tender inflamed, red, subcutaneous papules or plaque (on the face and limbs) that resolve spontaneously in a few days to a week but new crops may appear.
- Severe reactions may be accompanied by low-grade fever, malaise, lymphadenopathy symptoms of neuritis, and arthralgia.
- **Other features** include uveitis, iritis, orchitis, myositis, glomerulonephritis, edema, anemia, leukocytosis, and abnormal liver function tests.

Diagnosis of Leprosy

- **Clinical diagnosis** is by cardinal signs of leprosy: Hypopigmented/reddish patches with loss of sensation and thickening of peripheral nerves
- **Slit-skin smears:** The smears are made from skin lesions (earlobes and dorsum of the ring or middle finger) by scraped-incision method and the dermal material (fluid obtained) on to a glass slide and stained for acid-fast bacilli (AFB). It is useful in borderline lepromatous (BL) and LL.
- **Nasal secretions** for AFB from LL show numerous bacilli.
- **Lepromin test:** Lepromin is an antigen extract of dead *M. leprae*. The test is performed like the tuberculin test by intradermal injection of lepromin but is read after 4 weeks. It is **not a diagnostic test** for leprosy. It is **used for classifying** the leprosy based on the immune response. It is **interpreted** as follows:

  - **Lepromatous leprosy** shows **negative lepromin test** due to suppression of cell-mediated immunity.
  - **Tuberculoid leprosy** shows **positive lepromin test** because of delayed hypersensitivity reaction.
  - **Borderline leprosy:** Negative or weakly positive responses
- **Skin biopsy:** Involvement of peripheral nerves in a skin biopsy taken from the affected area is pathognomonic, even in the absence of bacilli. Lepra bacilli can be demonstrated in LL and BL types by Fite–Ferraco stain.
- **Serological test** is not sensitive or specific enough for diagnosis.
  - Hypergammaglobulinemia is common in LL and can give false-positive serological tests (VDRL, rheumatoid factor, and antinuclear antibodies).
  - IgM antibodies to PGL-1 (phenolic glycolipid-1) may be found in 95% of LL and in 60% of TT. However, these antibodies may also be present in normal individuals.
- **PCR testing** for *M. leprae* DNA: Detection of *M. leprae* DNA is possible in all types of leprosy using the polymerase chain reaction, but not sensitive or specific enough for diagnosis. It can be used to assess the efficacy of treatment.

Q. DR9.5 **Enumerate the indications and describe the pharmacology, administration, and adverse reaction of pharmacotherapies for various classes of leprosy based on national guidelines.**

Q. **Describe the treatment of leprosy based on the World Health Organization (WHO) guidelines.**

Multibacillary leprosy (MB): Duration of treatment is 1 year/12 months
- **Regimen 1:**
  - Dapsone 2 mg/kg daily (maximum 100 mg)
  - Clofazimine 50 mg daily or 100 mg three times a week
  - Rifampicin 450 mg (for patients <35 kg) or 600 mg (for patients <35 kg), on 2 consecutive days in a month
- **Regimen 2:**
  - Dapsone 100 mg daily (self-administered)
  - Clofazimine 50 mg daily (self-administered) + 300 mg once a month (supervised)
  - Rifampicin 600 mg once a month (supervised)

Paucibacillary leprosy (PB): Duration of treatment is 6 months
- Dapsone 100 mg given daily
- Rifampicin 600 mg is given once a month under supervision
- Clofazimine 50 mg daily (self-administered) + 300 mg once a month (supervised)—New addition in 2020

Treatment

Drugs

- Main drugs available include dapsone (100 mg), rifampicin (600 mg), clofazimine (100 mg), ethionamide (500 mg), and thiacetazone (150 mg). Other drugs effective against leprosy are ofloxacin, minocycline, and clarithromycin.
- **Side effects** of various drugs are as follows:
  - **Dapsone:** Hemolysis, agranulocytosis, hepatitis, and exfoliative dermatitis (**Box 19.24**)
  - **Clofazimine:** They are mainly found in the skin (e.g., reddish pigmentation of skin and ichthyosis) and intestinal tract (e.g., diarrhea and cramping abdominal pain).

Box 19.24: Dapsone resistance cases.
- Clofazimine alone, or
- Clofazimine + ethionamide 500 mg daily and rifampicin given on the first 2 days of each month

Treatment regimens for leprosy

There are two recommended regimens for multibacillary and one for paucibacillary leprosy (**Table 19.15**).

TABLE 19.15: Treatment (WHO) regimens for leprosy.

Drug	*Indication*	*Mechanism*	*Side effects*
Rifampin	Paucibacillary, multibacillary	Bactericidal, RNA-Pol inhibitor	GI: abdominal pain, nausea, vomiting, diarrhea Dermatologic: pruritus, rash Renal: acute renal failure pseudo hematuria Hepatic: transient liver dysfunction, jaundice, induction of P450 enzymes
Dapsone	Paucibacillary, multibacillary	Bacteriostatic, antifolate	Dermatologic: rash Hematologic: agranulocytosis, hemolysis (severe if G6PD deficient), methemoglobinemia Other: drug fever
Clofazimine	Paucibacillary, multibacillary	Bacteriostatic, binds *M. leprae* DNA	Dermatologic: skin pigmentation that often resolves with drug cessation GI: nausea, vomiting, diarrhea

Contd...

Contd...

Drug	*Indication*	*Mechanism*	*Side effects*
Ofloxacin	Single-lesion paucibacillary	Bactericidal, DNA gyrase inhibitor	GI: nausea Dermatologic: rash, pruritus, photosensitivity CNS: seizures, headache, dizziness
Minocycline	Single-lesion paucibacillary	Bacteriostatic, inhibits protein synthesis via 30S	GI: nausea, vomiting, diarrhea, hepatotoxicity Dermatologic: photosensitivity Other: dental staining; therefore contraindicated in pregnant women, neonates, children <8 years old

(CNS: Central nervous system; GI: Gastrointestinal)

Box 19.25: Treatment of lepra reactions.

During lepra reactions, the chemotherapy for leprosy is maintained.

1. *Type 1 lepra reaction (reversal reaction)*:
   - **Mild cases:** Aspirin 600 mg 6 hourly
   - **Severe cases:** Start with prednisone 40–80 mg daily and reduce gradually over 3–9 months
2. *Type 2 lepra reaction (erythema nodosum leprosum):*
   - **Mild cases:** Aspirin 600 mg 6 hourly
   - **Severe cases:** Prednisone 1 mg/kg/day. If there is no response to steroids, add clofazimine (300 mg/day) or thalidomide (100 mg 4 times daily). The doses are slowly reduced over 1–3 months. If there is involvement of eyes, 1% hydrocortisone drops or ointment and 1% atropine drops is given.

ECTOPARASITES

Ectoparasites are parasites that live on the surface of its host.

SCABIES

Q. DR5.1 **Describe the etiology, microbiology, pathogenesis, natural history, clinical features, presentations and complications of scabies in adults.**

Scabies is an intensely itchy rash caused by the ectoparasitic mite, *Sarcoptes scabiei* var. *hominis*.

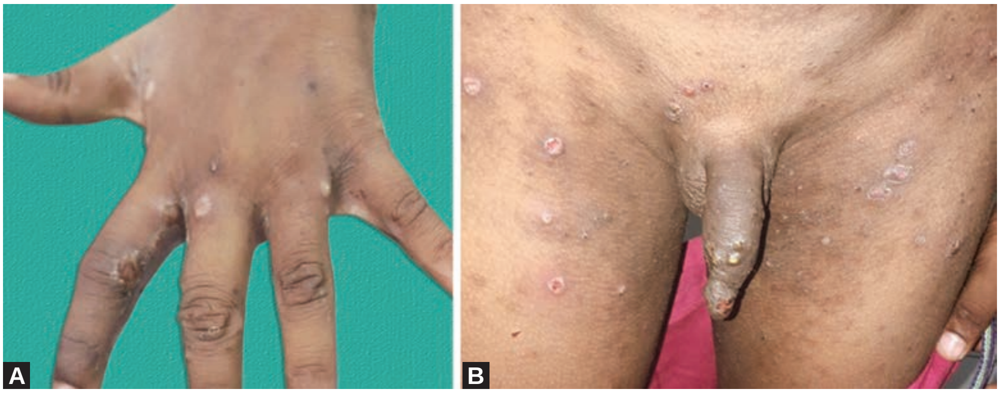
Age: It is most common in **children and young adults** but can occur at any age group.

Mode of Transmission

- **Person-to-person contact:** Scabies is a highly contagious. Newly fertilized female mites are transmitted from person to person by prolonged close/intimate personal contact (e.g., within households or institutions) with the skin and by sexual contact. This transmission is facilitated by social crowding, poor hygiene, and multiple sexual partners. In the absence of host contact, the mites usually die within a day or so. About 15–20 minutes of close contact with an infected individual is necessary for transfer of the mites from one individual to another.
- **Through contaminated clothes:** Transfer through clothes and bedding contaminated by infested patient immediately beforehand.

Clinical Features

- Scabies clinically present with itchy red papules (or occasionally vesicles and pustules). Itching/pruritus are worse at night.
- **Distribution of lesions:** It often suggests the diagnosis. Skin lesions can occur anywhere but rare on the face and scalp, except in infants. Sites of predilection are—(1) between the web spaces of the fingers (**Fig. 19.34A**) and toes, (2) on the palms and soles (more commonly in small children), (3) around the wrists and axillae, on the male genitalia (**Fig. 19.34B**), and around the nipples and umbilicus. **Circle of Hebra** is an imaginary circle intersecting sites of predilection and includes areolae, axillae, elbow flexures, wrists, finger webs, umbilicus, lower abdomen, and genitalia.
- **Pruritus/itching** is a prominent feature and usually intense and worse (most severe) at night and after a hot shower. The itching develops a few days after infestation. It may develop within a few hours, if the mite is infested for second time. It develops in the trunk and limbs, and usually not affects the scalp.
- **Generalized rash** of scabies appears as tiny red intensely itchy bumps on the limbs and trunk. It is due to an allergic reaction to the mites and their products. It may develop several weeks to develop after initial infestation.
- **Nodules:** Presence of itchy lumps or nodules in the armpits and groins or along the shaft of the penis is highly suggestive of scabies. Nodules may persist for several weeks or longer even after the successful eradication of living mite.



FIGS. 19.34A AND B: (A) Scabies involving the web spaces of the fingers; (B) Genital region of male.

- **Acropustulosis:** Blisters and pustules on the palms and soles of infants with scabies.
- **Pathognomonic sign:** It is the presence of **linear or curved skin burrows** in which the mites live. However, these are not always seen. Burrows are seen as dark wavy lines in the epidermis and measure up to 15 mm. Typical burrows may be only a few in number. Hence, they are often missed, if the skin has been scratched or become secondarily infected or if there is eczema. Microscopic examination of the contents of a burrow may show many mites, eggs, or mite feces (scybala).
- **Complication:** Excoriations and secondary bacterial infection may develop in the skin rash. Secondary infection of lesions of scabies due to nephritogenic streptococci may complicate the rash leading to poststreptococcal glomerulonephritis.

Diagnosis

- **Clinical grounds:** Scabies should be considered on the basis of clinical presentation and history. Diagnosis can be made in patients with itching and symmetrical skin lesions in characteristic distribution/locations. It may be obvious if there is a history of household/close contact with an affected patient.
- **Confirmation of scabies:** It is by **identifying the scabietic burrow** and **visualizing the mite**. Burrows should be unroofed with a sterile needle or scalpel blade. The skin scrapings of a lesion should be examined microscopically (by a potassium hydroxide preparation) for the mite and/or its eggs and its fecal pellets. Microscopic examination of clear adhesive tape lifted from lesions and skin biopsy also may be useful for diagnosis.
- **Dermoscopy**: The characteristic finding is a dark and triangular shape that represents the head of the mite within a burrow (“delta wing” sign).

Q. Write short note on crusted scabies/Norwegian scabies.

Crusted or Norwegian Scabies

- Crusted scabies, Boeck scabies, keratotic scabies, or Norwegian scabies is clinical variant of scabies characterized by hyperinfestation (huge numbers) of *Sarcoptes scabiei* mites in the skin.
- It is named Norwegian scabies because of its initial description in Norwegian patients with leprosy.
- **Predisposing conditions:** Patients are highly infectious. The number of mites rapidly increases (hyperinfestation) due to impaired immune response, lack of pruritus or patient’s with neurological disorders with physical inability to scratch. Disorders predisposing to crusted scabies are listed in **Table 19.16**. It may be associated with HLA-A11. Transmission through fomites can occur because mites survive on the sloughed skin in environment.

TABLE 19.16: Disorders predisposing to crusted scabies.

Disorders with defective T-cell response: AIDS, lymphoma, organ transplantation, and T-cell leukemia **Physical debilities:** Critical illness and kwashiorkor **Reduced sensation:** Leprosy	**Neurological disorders:** Parkinson’s disease, tabes dorsalis, and syringomyelia **Mental debilitation:** Down’s syndrome and mental retardation **Metabolic disorder:** Diabetes mellitus

- **Clinical features:** Patient presents with marked thickening and crusting of the skin (hyperkeratotic crusted lesions) particulars on the hands. However, entire body including the face and scalp is often involved. Nails often show hyperkeratosis. Pruritus is minimal or absent.

Q. DR5.3 Enumerate and describe the pharmacology, administration and adverse reaction of pharmacotherapies for scabies.

Treatment (Table 19.17)

Principles of Scabies Treatment

- Topical treatment of the patient and all asymptomatic close contacts (family members/physical contacts) should be done simultaneously to ensure eradication.
- Include a scabicidal and a keratolytic in the treatment.
- To avoid reinfection, washing, or cleaning of recently worn clothes (including underclothing) and bed linen (preferably at 60°C) is recommended.

Topical Treatment

- **Areas of application:** Scabicides are applied thinly and thoroughly to all over the skin below the neck (including the genitalia, palms and soles, and under the nails). Reapply topical scabicide to the hands, if patient washed it during the treatment period.
- **Duration of treatment:** Usually, effectively treated scabies infestations become noninfectious within a day. However, even after successful treatment, pruritus/itching and rash may remain even up to 4 weeks. Unnecessary retreatment may cause contact dermatitis.
- **Repetition of application:** Topical application should be repeated after 1 week.

Topical Scabicide

These include—(i) precipitated sulfur 2–10% in petrolatum, (ii) benzyl benzoate 10–25%, (iii) crotamiton 10%, (iv) Lindane (gamma benzene hexachloride) 1%, (v) permethrin 5%, and (vi) malathion 0.5%.

TABLE 19.17: Typical treatment of scabies.

Drug name	***Dose***	***Major side effects or contraindications***
Topical treatment		
Permethrin	➢ 5% cream ➢ Rinsed off after 8–14 hours	➢ Itching and stinging on application ➢ May be used in infants ≥2 months of age, children, pregnant women and nursing mothers ➢ Skin rash, diarrhea and rarely convulsion and death
Benzyl benzoate	➢ 10% or 25% lotion ➢ Rinsed off after 24 hours (several other regimens possible)	Burning and stinging when applied to excoriated skin, pruritic cutaneous xerosis, or eczematous lesions post-treatment
Malathion	➢ 0.5% lotion or cream ➢ Rinsed of after 24 hours	Skin irritation but major side effect rate
Crotamiton	➢ 10% cream ➢ Applied to nodules for 24 hours, rinsed off and reapplied for an additional 24 hours	Skin rash

Oral Therapy Ivermectin

- **Dose:**
  - Single oral dose 200 µg/kg in otherwise healthy individuals and side effects are rare.
  - Two doses of oral ivermectin (200 µg/kg, as 2 doses 2 weeks apart) are easy to use and as effective as topical therapy. Two doses are indicated in crusted scabies or Norwegian scabies. The toxic effects with two doses are insignificant.
- Oral antihistamines can alleviate the hypersensitivity response.

LICE INFECTION

Q. DR6.1 Describe the etiology, pathogenesis and diagnostic features of pediculosis in adults.

Lice are blood-sucking ectoparasites and can infest human in three ways:

1. **Head lice (pediculosis capitis):**
   - Infestation with the head louse, *Pediculus humanus capitis*, is common worldwide.
   - **Age and gender:** Predominantly affects children and more common in females.
   - **Spread:**
     - It is highly contagious and spread by direct head-to-head contact and is associated with overcrowding.
     - It may be indirectly spread through hats, clothes, or pillow covers.
   - **Clinical presentation:** Head lice usually presents with scalp itch that leads to scratching, scalp excoriations, secondary infection (important cause of impetigo) and cervical lymphadenopathy. Itching may produce sleep disturbances and difficulties in concentration and the affected children may perform poorly in school.

- **Diagnosis:** Confirmed by identifying the living louse or nymph or empty egg cases ("nits" look like whitish shells stuck to the hair shaft on the scalp and are difficult to dislodge).

Treatment
- Apply **malathion or permethrin or carbaryl or phenothrin in lotion or aqueous formulations**, twice at an interval of 7–10 days (with a contact time of 12 hours). If treatment with one fails, a different insecticide is used for the next course. Rotational treatments within a community can avoid resistance. Treatment is usually repeated after 7 days.
- Regular "wet-combing"(physical removal of live lice by regular combing of conditioned wet hair, metal nit combs may help remove the eggs) is less effective than pharmacological applications.
- Apply Vaseline to eyelashes/brows twice daily for at least a fortnight.
- **Resistant cases:** Use oral ivermectin (400 µg/kg as two doses 1 week apart)
- Treatment of secondary bacterial infection if present

2. **Body lice (pediculosis corporis):**
   - Body lice are ectoparasites similar to head lice but they live on clothing (e.g., seams), and feed on the skin.
   - **Predisposing factors** include poor hygiene, poverty, neglect, and overcrowded conditions. It is rare in developed countries (except in homeless and vagrants).
   - **Spread:** By direct contact or sharing infested clothing. The lice and eggs are commonly found on the clothing but are rarely observed on the skin of the patient.
   - **Clinical presentation:** It presents with itch, excoriations, and secondary infection. Sometimes, there may be postinflammatory hyperpigmentation of the skin.

Treatment: By malathion or permethrin. Dry cleaning and high temperature washing or insecticide treatment for the clothes is helpful.

3. **Pubic lice (Crab lice or *Phthiriasis pubis*):**
   - Pubic louse *(Phthirus pubis)* is a bloodsucking insect that attaches tightly to the pubic hair.
   - **Mode of transmission:** Usually, it is sexually acquired (direct contact) and transferred only by close bodily contact. The lice lay its eggs (nits) at hair bases and usually hatch within a week.
   - **Clinical presentation:** It may be asymptomatic or presents with severe itching, especially at night. It usually infests public hair and occasionally other hairy areas (eyebrows, eyelashes, and the beard). Lice can be seen near the base of the hair with eggs.

Treatment: Similar to head lice and the treatment of choice is malathion or carbaryl in an aqueous base. They are applied on two occasions to the whole body, because it can also infest body hair. All sexual contacts (patient's partner) should also be treated. Patient should be screened for other sexually transmitted diseases. Infestation of the eyelashes and eyebrows is treated with application of white soft paraffin three times daily for 1–2 weeks.

SEXUALLY TRANSMITTED INFECTIONS

Sexually transmitted diseases (STDs) are a group of communicable diseases that are transmitted predominantly by sexual contact and caused by a wide range of bacterial, viral, protozoal, and fungal agents and ectoparasites (**Table 19.18**).

Gonorrhea

Q. DR10.10 **Describe the etiology, diagnostic and clinical features and management of gonococcal and non-gonococcal urethritis.**

Definition: Gonorrhea is a sexually transmitted infection (STI) due to the gram-negative diplococcus, *Neisseria gonorrhoeae*. It commonly infects columnar epithelium in the lower genital tract (cervicitis and urethritis), rectum (proctitis), and eye (conjunctivitis).

Mode of transmission: Genital–genital, genital–anorectal, or orogenital or oroanal contact or from mother to child transmission during delivery.

Incubation period: Usually 2–10 days following exposure.

TABLE 19.18: Sexually transmitted infections.

Bacterial agents:
- *Neisseria gonorrhoeae*
- *Chlamydia trachomatis*
- *Haemophilus ducreyi*
- *Mycoplasma hominis*
- *Ureaplasma urealyticum*
- *Calymmatobacterium granulomatis*
- *Shigella* species
- Group B *Streptococcus*
- Bacterial vaginitis associated organisms

Protozoal agents:
- *Entamoeba histolytica*
- *Giardia lamblia*
- *Trichomonas vaginalis*

Viral agents:
- Human (alpha) herpesvirus
- Human (beta) herpesvirus
- Hepatitis B virus
- Human papillomavirus
- Molluscum contagiosum virus
- Human immunodeficiency virus

Fungal agents: *Candida albicans*

Ectoparasites:
- *Phthirus pubis*
- *Sarcoptes scabiei*

Clinical Features

- **Gonococcal infections in men: Acute urethritis** is the most common clinical manifestation and presents with urethral discharge and dysuria usually without urinary frequency or urgency. On examination, urethra shows mucopurulent discharge that may be accompanied by erythema of the urethral meatus.
- **Gonococcal infections in women:** Gonococcal cervicitis and vaginitis present with symptoms related to endocervical and urethral infection and include scant vaginal discharge and dysuria. Gonococci may infect the urethra, paraurethral glands/ducts, and Bartholin's glands/ducts. It may be asymptomatic in up to 80% of women.
- **Anorectal and pharyngeal gonorrhea** are usually asymptomatic.
- **Ocular gonorrhea:** Gonococcal conjunctivitis is an uncommon. It may present with purulent discharge from the eye(s), inflammation of the conjunctivae and edema of the eyelids, pain, and photophobia. Gonococcal ophthalmia neonatorum also presents with purulent conjunctivitis and edema of the eyelids. Conjunctivitis must be treated early to prevent corneal damage.
- **Disseminated gonococcal infection (DGI):** Dissemination can result in gonococcal bacteremia and is rare and develops in women with asymptomatic genital infection. Symptoms include arthritis of one or more joints (asymmetric and migratory), pustular skin lesions, fever, and tenosynovitis. Gonococcal endocarditis or meningitis may rarely occur.
- **Acute perihepatitis (Fitz–Hugh–Curtis syndrome)** is a rare complication of PID, and is thought to occur through direct extension of *N. gonorrhoeae* from fallopian tube to liver capsule and peritoneum along the paracolic gutters. Patients present with sharp, pleuritic right upper quadrant pain.

Diagnosis

- **Gram staining and culture** of urethral exudates, genital, rectal, pharyngeal, or ocular secretions show gram-negative intracellular monococci and diplococci.
- **Sterile pyuria:** Urine may show polymorphonuclear leukocytes with a negative urine culture report.
- **Nucleic acid probe tests:** Nucleic acid amplification tests (NAATs) are more sensitive than culture. They can be performed on urine samples, swabs from endocervix, urethra, rectum, and pharynx.
- Direct antigen detection by fluorescein-conjugated monoclonal antibodies and direct fluorescence microscopy
- Enzyme-linked immunoassays for the detection of gonococcal antigen
- Blood cultures in disseminated disease.

Complications

If untreated infection can develop following complications:

- **In females:** It causes pelvic inflammatory disease PID (pelvic inflammatory disease). Local complications such as endometritis, salpingitis, tubo-ovarian abscess, bartholinitis, peritonitis, and perihepatitis
- **In male patients:** Periurethritis, epididymitis epididymo-orchitis, and prostatitis
- **Newborns:** Ophthalmia neonatorum in newborns

Box 19.26: Treatment of gonorrhea.

- One of the following regimens is recommended at present:
  - Cefixime 400 mg orally (single dose)
  - Ceftriaxone 250 mg intramuscularly (single dose)
  - Spectinomycin 2 g intramuscularly (single dose)
- If quinolone and azithromycin resistance is not a problem:
  - Ciprofloxacin 500 mg orally (single dose)
  - Ofloxacin 400 mg orally (single dose)
  - Levofloxacin 250 mg orally (single dose)
  - Azithromycin 2 g orally (single dose)
- For epididymo-orchitis, doxycycline 100 mg twice daily for 14 days along with one dose of ceftriaxone or ciprofloxacin

Treatment of Gonorrhea

See **Box 19.26**.

Nongonococcal Urethritis

Q. List the etiology and drugs used in nongonococcal urethritis.

Etiology

See **Table 19.19**.

Signs and Symptoms

Symptoms and signs of gonococcal urethritis and nongonococcal urethritis are similar but differ significantly in severity.

TABLE 19.19: Causes of nongonococcal urethritis.

***Chlamydia trachomatis* (15–40%)**	***Mycoplasma genitalium* (15–25%)**
Others (20–50%): ➢ *Trichomonas vaginalis* ➢ *Ureaplasma urealiticum* ➢ Herpes simplex virus (in absence of skin lesions) ➢ Adenovirus ➢ *Haemophilus*	*Miscellaneous*: In association with urinary tract infection, bacterial prostatitis, urethral stricture, phimosis, secondary to instrumentation of the urethra, congenital abnormalities, chemical irritation, and tumors

Diagnosis

- **Gram staining** of **discharge or sediment** of first voided urine (symptomatic/asymptomatic)
- Direct fluorescence assay
- Enzyme immunoassay
- Hybridization assay
- Nucleic acid amplification tests

Treatment

STD treatment guidelines from the CDC, and the WHO recommends:

- **Doxycycline 100 mg twice daily** for 7 days, **or**
- **Azithromycin 1 g orally**

Alternatives

- Erythromycin base 500 mg four times for 7 days, or
- Ofloxacin 300 mg twice daily for 7 days, or
- Levofloxacin 500 mg once daily for 7 days

General features

- All sex partners in last 60 days should be evaluated and treated
- Sexual abstinence till completion of treatment
- Patients should be reviewed 2–3 weeks after treatment to confirm resolution of symptoms and treatment of sexual contacts
- Patients should be checked for other STIs including syphilis and HIV. Results of tests should be checked during review.

Enumerate the Differences Between Gonococcal and Nongonococcal Urethritis

There are certain differences between gonococcal and nongonococcal urethritis.

Gonococcal urethritis	*Nongonococcal urethritis*
➢ Incubation period is 2–5 days	➢ Incubation period is 2–3 weeks
➢ Onset of symptoms is abrupt	➢ Associated symptoms are less severe
➢ Associated symptoms are usually severe	➢ Patients usually have a smarting feeling while passing urine
➢ Patients present with intense burning sensation while passing urine	➢ Discharge is usually mucoid/mucopurulent. There may be manifestation may be crusting in the perimeatal area in the morning
➢ Discharge is profuse and yellowish green	➢ Fever and malaise are less commonly seen
➢ Fever and malaise may be seen	

Chancroid

Q. **Write short essay/note on clinical features and treatment of chancroid.**

- Chancroid or soft chancre is an acute sexually transmitted infection caused by *Haemophilus ducreyi*. It is characterized by painful genital ulcerations and inguinal adenitis.
- The genital ulceration in chancroid increases the efficiency of transmission and the degree of susceptibility to HIV in infection.
- Coinfection with *Treponema pallidum* and herpes simplex is observed in 10% of cases.

Clinical Features

- *Incubation period*: Usually 3–10 days
- Infection is acquired due to a break in the epithelium during sexual contact with an infected individual
- **Lesions in the external genitalia:**
  - **Sites of lesions:** Prepuce and frenulum in men and vaginal entrance and the perineum in women. At the site of inoculation (the external genitalia), an initial erythematous papule appears, which then breaks down within 2–3 days into a classic chancroidal ulcer.
  - **Characteristics of ulcer:** The chancroid ulcer is superficial, circumscribed, and painful. Ulcers have ragged and undermined edges, and necrotic base bleeds easily and generally not indurated. Ulcer may be single. If multiple, they may merge to form giant serpiginous ulcer.
- **Lymphadenopathy:** About 50% of patients develop enlarged, painful, and tender inguinal lymph nodes (usually unilateral). The involved nodes become matted and progress to form large unilocular buboes, which suppurate.

Diagnosis

- It is based on the microscopic identification and culture isolation of *Haemophilus ducreyi* in scrapings from ulcer or pus from bubo.
- Polymerase chain reaction (PCR) technique not commercially available
- Detection of antibody to *H. ducreyi* using EIA may be useful.

Box 19.27: Treatment options for chancroid.

- Azithromycin, 1 g orally, as a single dose, or
- Ceftriaxone, 250 mg by intramuscular injection as asingle dose, or
- Ciprofloxacin, 500 mg orally, twice daily for 3 days, or
- Erythromycin base, 500 mg orally 4 times daily for 7 days

Treatment of chancroid (Box 19.27)

Sex partners of chancroid patients should be examined and treated, if they had sexual contact with the patient during the 10 days preceding the patient's onset of symptoms. This is regardless of whether they have symptoms of the disease or not.

CHLAMYDIAL INFECTIONS

Chlamydial infections may be asymptomatic or cause:

- **In male:** Urethritis, epididymitis, and prostatitis. Untreated infection can cause infertility and reactive arthritis.
- **In female:** Cervicitis and salpingitis. Most of the infected females are asymptomatic and are likely to develop complications such as PID, infertility, or ectopic pregnancy.

Lymphogranuloma Venereum

Q. Write a short note on lymphogranuloma venereum (LGV).

It is a sexually transmitted disease caused by *Chlamydia trachomatis* (types LGV 1, 2, and 3).

Clinical Features

- **Incubation period:** 3–30 days.
- **Stages:** Three characteristic stages—
    1. **Primary genital lesion:** LGV starts as an asymptomatic small painless papule at the site of inoculation (external genitalia) and tends to ulcerate.
    2. **Regional lymphadenopathy:** Within a few days to weeks, the ulcers heal and regional lymphadenopathy (usually unilateral) develops. The lymph nodes are initially discrete painful and fixed and the overlying skin appears dusky and erythematous.
    3. **Buboes:** Later in the course, the lymph nodes may become matted, fluctuant (buboes), and rupture. The overlying skin becomes thinned, inflamed, and fixed. Finally, multiple draining fistulae may occur. Extensive enlargement of inguinal lymph nodes above and below the inguinal ligament **("groove sign")** can develop.
- **Other features:**
    - Acute LGV can also cause proctitis with perirectal abscesses, which may resemble anorectal Crohn's disease.
    - **Chronic phase:** Chronic infection may produce extensive scarring, abscess and sinus formation. The destruction of local lymph nodes can produce lymphedema of the genitalia.
    - **Constitutional symptoms:** These include fever, chills, headache, anorexia, meningismus, myalgia, and arthralgia.

Diagnosis

- **Detection of nucleic acid (DNA):** Direct immunofluorescent antibody and nucleic acid amplification tests are positive, which should be confirmed by real-time PCR for LGV-specific DNA.
- **Isolation of the LGV (L1–3 serotypes) strain of Chlamydia:** Tissue culture from swab obtained from ulcer-aspirated bubo pus, rectum, urethra, endocervix, or from other infected tissue is the most specific test; however, sensitivity is only 75–85%.
- **Serological tests:** Microimmunofluorescence (micro-IF) test and complement fixation test (CF) to detect antibodies
- Frei skin test is not useful.

Treatment (Box 19.28)

- Early treatment is necessary to prevent the chronic phase.
- Fluctuant buboes should be aspirated with a syringe and needle.
- Surgical drainage or reconstructive surgery may be sometimesneeded.

Box 19.28: Treatment options for lymphogranuloma venereum.

- Doxycycline, 100 mg orally, twice daily for 14 days, or
- Erythromycin, 500 mg orally, 4 times daily for 14 days, or
- Tetracycline, 500 mg orally, 4 times daily for 14 days

GRANULOMA INGUINALE (DONOVANOSIS)

Q. Write short note on granuloma inguinale (donovanosis).

Granuloma inguinale is a genital ulcerative disease caused due to intracellular gram-negative bacterium *Klebsiella granulomatis* formerly known as *Calymmatobacterium granulomatis* (Donovan bodies).

Incubation period: 3–40 days

Clinical Features (Genital Lesions)

- Painless and progressive ulcerative lesions without regional lymphadenopathy
- Genital lesions are highly vascular, produce "beefy red appearance", and bleed easily on touch. However, it can also produce hypertrophic granulomatous, necrotic, or sclerotic lesions.

Diagnosis

Microscopy examination of material from the lesion (tissue crush preparation or biopsy) shows dark staining intracellular bipolar-staining Donovan bodies. The causative organism is difficult to culture.

Treatment

- Treatment will prevent the progression of lesions. Treatment should be continued until all lesions havecompletely epithelialized.
- Treatment with antibiotics is needed for at least 3 weeks. Effective regimens are presented in **Box 19.29**.

Box 19.29: Treatment options for granuloma inguinale.

- Azithromycin, 1 g orally on the 1st day, then 500 mg orally, once a day, or
- Doxycycline, 100 mg orally, twice daily, or
- Erythromycin, 500 mg orally, 4 times daily, or
- Tetracycline, 500 mg orally, 4 times daily, or
- Trimethoprim 80 mg/sulfamethoxazole 400 mg, 2 tablets orally, twice daily

SYPHILIS

Q. DR10.1, 10.2 Classify syphilis based on the presentation and clinical manifestations.

Syphilis (lues) is a **chronic,** systemic infection **caused by spirochete *Treponema pallidum*,** which is usually **sexually transmitted.**

Spirochetes are gram-negative and slender corkscrew shaped.

Source of Infection

Contact with an open infectious lesion of **primary or secondary syphilis**. Lesions in the mucous membranes or skin of the genital organs, rectum, mouth, fingers, or nipples. These lesions include chancre, mucous patch, skin rash, or condylomata lata.

Mode of Transmission

- **Sexual contact:** It is the usual mode of spread.
- **Transplacental transmission:** From mother with active disease to the fetus (during pregnancy) → congenital syphilis
- **Blood transfusion**
- **Direct contact** with the open lesion is rare mode of transmission.
  Transmission from a mother to her fetus and rarely by blood transfusion is possible for several years following infection.
- *Treponema pallidum* can penetrate intact mucous membranes or abraded skin rapidly and gain entry into the lymphatics and bloodstream and produce systemic infection.

Classification (Table 19.20 and Fig. 19.35)

TABLE 19.20: Classification of syphilis.

Acquired syphilis	*Congenital syphilis*
➢ Primary syphilis ➢ Secondary syphilis ➢ Latent syphilis ➢ Late syphilis (tertiary): – Late latent – Benign tertiary – Quaternary syphilis (cardiovascular and neurosyphilis)	➢ Intrauterine death and perinatal death ➢ Early (infantile) ➢ Late (tardive)

Acquired Syphilis

Primary syphilis

Primary chancre: It is the classical lesion of primary syphilis.

- **Location:** The primary chancre develops at the site of inoculation.
  - **In males: Penis or scrotum** in males (in heterosexual) and in homosexual males, it may occur in the anal canal, rectum, fingers, or within the mouth.
  - **In females: Cervix, vulva,** and **vaginal** wall

- Primary chancre (**Fig. 19.36**) is single, firm, **non-tender (painless)**, slightly raised, **red papule** (chancre) up to several centimeters in diameter. It rapidly becomes eroded to create a clean-based shallow ulcer. Because of the induration surrounding the ulcer, it is designated as **hard chancre.**

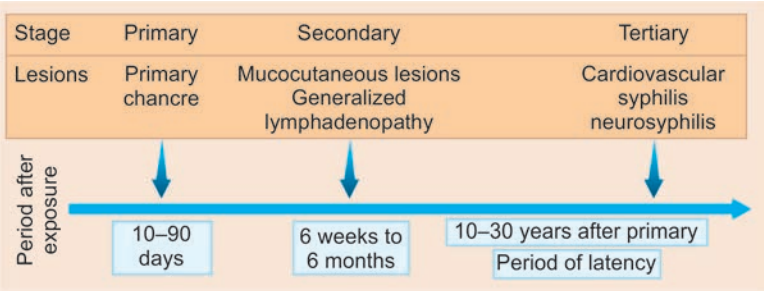


FIG. 19.35: Course of syphilis (if untreated).

Regional lymphadenitis: Usually accompanies the primary chancre within 1 week of the onset of the lesion.

- The lymph nodes are firm, rubbery, mobile, nonsuppurative, painless, and nontender.
- Chancres on external genitalia and anus produce bilateral inguinal lymphadenopathy, whereas those on cervix and vagina cause iliac or perirectal lymphadenopathy.

Fate: Even without therapy, the primary chancre heals within 4–6 weeks, but the lymphadenopathy may persist for months.

- Primary syphilis in HIV-positive patients is often asymptomatic and they frequently present with secondary or latent syphilis.

Secondary syphilis

Secondary syphilis develops 4–10 weeks after the primary chancre in approximately 75% of untreated patients. Its manifestations are due to systemic spread and proliferation of the spirochetes within the skin and mucocutaneous tissues. It starts with symptoms of generalized infection such as malaise, sore throat, headache, low-grade fever, and arthralgia.

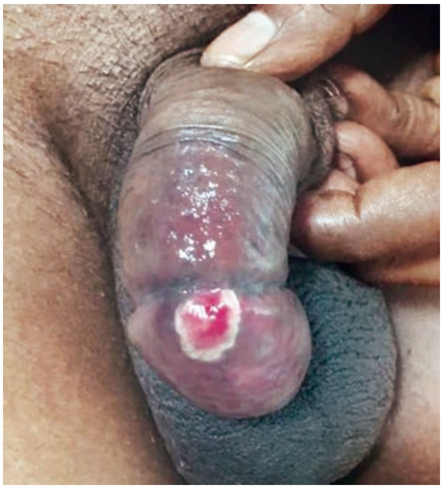

FIG. 19.36: Primary chancre in primary acquired syphilis.

Lesions

Mucocutaneous lesions: These are painless and superficial lesions and contain spirochetes and are infectious.

- **Skin rashes (75%):** They begin as **discrete red-brown macules** <5 mm in diameter. They are generalized symmetrical and nonirritable but more frequent on the trunk and proximal limbs. These macular lesions may progress to a scaly/pustular/ annular or necrotic ulcers, which frequently involve the palms (**Fig. 19.37A and B**) and soles. The lesions are initially red, changing to a "gun–metal" gray as they resolve.
- **Condylomata lata (10%)** (**Fig. 19.37B**): These are **broad-based,** moist, pink, or gray–white, **elevated plaques** (papules coalescing to plaques)**,** highly infectious containing numerous spirochetes. They are seen in moist, warm, intertriginous areas of the skin, such as the **anogenital region (perineum, vulva, and scrotum)**, inner thighs, and axillae.
- **Mucosal lesions (30%):** These usually occur in the mucous membranes of **oral cavity (lip, oral mucosa,** tongue, palate, and pharynx) **or** vulva, vagina, or glans penis **as silvery-gray superficial** mucosal **erosions**. They are surrounded by a red serpiginous periphery and are usually painless. Rarely, they may coalesce to produce characteristic "snail track" ulcers in the mouth.
- These lesions contain numerous *T. pallidum* and are the **highly infectious.**
- **Microscopy:** Similar to primary chancre, i.e., infiltration by plasma cells and endarteritis obliterans.

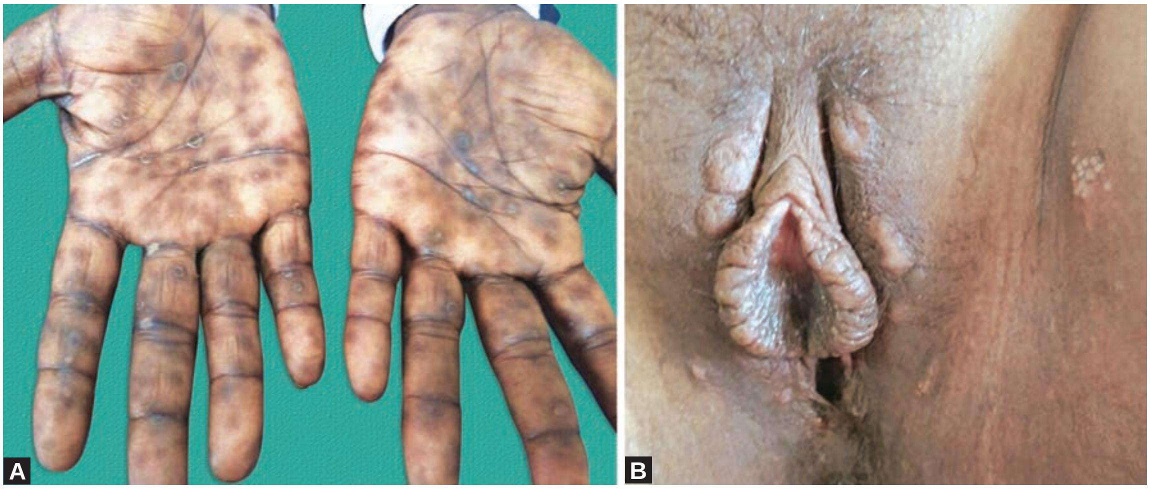
Generalized painless lymphadenopathy: Generalized, firm nontender lymphadenopathy (shotty) occurs in about 50% of patients. They involve especially **epitrochlear nodes** and show plenty of spirochetes. Mild fever, malaise, and weight loss are common in secondary syphilis, which may last for several weeks. The lesions subside even without treatment.

Less common manifestations include meningitis, cranial nerve palsies, anterior or posterior uveitis, hepatitis, gastritis, glomerulonephritis (proteinuria, nephrotic syndrome, or hemorrhagic glomerulonephritis), or arthritis and periostitis.

Latent syphilis

Without treatment, the clinical manifestations of secondary syphilis will resolve over 3–12 weeks. In an untreated (about 30%) patient during this phase, there is no evidence of clinical disease but it shows the presence of positive syphilis serology or the diagnostic cerebrospinal fluid (CSF) abnormalities of neurosyphilis. This is known as latent syphilis and is divided into:

- *Early latency (within 1 year of infection):* During this period, syphilis may be transmitted sexually.
- *Late latency (begins at 1 year of infection)*: During this period, the patient is no longer sexually infectious. Pregnant women with latent syphilis may infect the fetus in utero.



FIGS. 19.37A AND B: (A) Symmetrical skin rashes of secondary syphilis on palm; (B) Condyloma lata.

Late (tertiary) syphilis

- **Late latent syphilis:**
  - This phase may persist for many years or for life.
  - No symptoms or signs of syphilis
  - More than 60% of patients suffer little or no ill health even without treatment.
- **Benign tertiary (gummatous) syphilis:**
  - It is called benign because of its response to therapy rather than its clinical manifestations.
  - It may develop after 3–10 years after initial infection.
  - *Structures involved*: Skin (frequently at sites of trauma as nodules or ulcers), mucous membranes (mouth, pharynx, larynx, or nasal septum appears as punched-out ulcers), bone (e.g., skull, tibia, fibula, and clavicle) muscle, or viscera (e.g., liver hepar lobatum and spleen).
  - *Characteristic feature*: It is a chronic granulomatous (sometimes ulcerating) lesion called a gumma, which may be single or multiple.
  - *Consequences*: Healing with scar formation may damage the function of the structure involved.
- **Quaternary syphilis**: **Neurosyphilis and cardiovascular syphilis may coexist and sometimes called as quaternary syphilis.**
  - *Cardiovascular syphilis*:
    - It may present many years after initial infection.
    - Most **frequently involves the aorta** (the ascending aorta aortic valve and/or the coronary ostia, the aortic arch) and known as syphilitic aortitis
    - Clinical features include angina, features of aortic incompetence, and aortic aneurysm.
  - **Neurosyphilis** (discussed in Chapter 16).

Congenital Syphilis (Box 19.30)

Q. DR10.4 Write short note on congenital syphilis.

- ***Transplacental transmission*:** *T. pallidum* can cross placenta and spread from infected **mother to the fetus** (during pregnancy).
- Transmission occurs, when **mother is suffering from primary or secondary syphilis** (when the spirochetes are abundant). Because routine serologic testing for syphilis is done in all pregnancies, congenital syphilis is rare.

Box 19.30: Stigmata of congenital syphilis.

- Hutchinson's incisors (anterior–posterior thickening with notch on narrowed cutting edge)
- Mulberry molars (imperfectly formed cusps/deficient dental enamel)
- High-arched palate
- Maxillary hypoplasia
- Saddle nose
- Rhagades (radiating scars around mouth, nose, and anus following rash)
- Salt and pepper scars on retina (from choroiditis)
- Corneal scars (from interstitial keratitis)
- Sabre tibia (from periostitis)
- Bossing of frontal and parietal bones (healed periosteal nodes)

Manifestations

It can be divided into:

- **Intrauterine death and perinatal death**
- **Early (infantile) congenital syphilis:** It manifests within the **first 2 years of life** and often manifested by **nasal discharge** (rhinitis) and congestion (**snuffles**). They resemble features of secondary syphilis.
    - A desquamating or bullous eruption/rash can lead to epidermal sloughing of the skin, mainly in the hands, feet, around the mouth, and anus. It also may show condyloma lata.
    - *Skeletal abnormalities*: Syphilitic osteochondritis (inflammation of bone and cartilage is more distinctive in the nose → produces characteristic saddle nose deformity); syphilitic periostitis (involves the tibia and leads to anterior bowing or saber shin)
    - Others organs involved are **liver** (diffuse fibrosis) and **lung** (airless-**pneumonia alba**).
- **Late (tardive) congenital syphilis:**
    - Manifests 2 years after birth, and about 50% of untreated children with neonatal syphilis will develop late manifestations and take the form of "stigmata" relating to early damage to developing structures, particularly teeth and long bones.
    - Distinctive manifestation in Hutchinson's triad are—(1) interstitial keratitis, (2) Hutchinson's teeth, and (3) eighth-nerve deafness. Other features include Clutton's joints, neurosyphilis, gummatous periostitis, destruction of palate, and nasal septum. Cardiovascular involvement is rare. Stigmata of congenital syphilis are listed in **Box 19.30**.

Laboratory Diagnosis

Q. Write short note/essay on:

- Tests for diagnosis of syphilis
- Serological tests for syphilis
- Venereal Diseases Research Laboratory (VDRL) test

Demonstration of Treponema Pallidum

- **Dark-field microcopy:** Most sensitive and specific method is identification in serum collected from primary chancres, or from moist or eroded mucous lesions in secondary syphilis by dark-field microscopy. It shows drifting rotary motion (corkscrew) of *Treponema pallidum*. Patients with either primary or secondary disease are highly infectious.
- **Direct fluorescent antibody *T. pallidum* (DFA-TP) test**: In fixed smears from the chancre, it is important for diagnosis in primary syphilis.
- Microscopic demonstration of *Treponema pallidum* in tissues stained by appropriate stains and PCR are also useful.

Serological Tests

- **Nontreponemal antibody (nonspecific) tests:** These tests measure antibody to cardiolipin, a phospholipid presents in both host tissues and *T. pallidum*. These tests include:
    - **Venereal Diseases Research Laboratory (VDRL) test**
    - Rapid plasma reagin (RPR) test
- **Treponemal (specific) antibody tests:** They measure antibodies, which react with *T. pallidum*.
- **Significance—**
    - Used for confirmation. They are highly specific for treponemal disease. However, they do not differentiate between syphilis and other treponemal infection (e.g., as yaws).
    - In most of the patients, these tests usually remain positive for life, regardless of treatment or disease activity. However, 15–25% of patients treated in primary stage become nonreactive after 2–3 years.
    - Various tests include:
        - Treponemal antigen-based enzyme immunoassay (EIA) for IgG and IgM
        - *T. pallidum* hemagglutination assay (TPHA)
        - *T. pallidum* particle agglutination assay (TPPA)
        - Fluorescent treponemal antibody absorption (FTA-ABS) test

Examination of CSF: In benign tertiary and cardiovascular syphilis, CSF should be examined because of coexistence of asymptomatic neurological disease. CSF should be examined in neurosyphilis and in both early and late congenital syphilis.

Other tests: Chest X-ray, electrocardiogram (ECG), and echocardiogram are necessary in cardiovascular syphilis. Biopsy may be necessary to diagnose gumma.

Q. DR10.3 Enumerate the indications and describe the pharmacology, administration, and adverse reaction of pharmacotherapies for syphilis.

Management (Table 19.21)

- **Patients allergic to penicillin**: In primary, secondary, and early latent syphilis, these patients should be given tetracycline or doxycycline for 2 weeks and in late latent syphilis, it should be given for 4 weeks.
- **Ceftriaxone:** It may be given in the dose of 1 g once a day for 10–14 days.
- **Azithromycin:** Single dose of 2 g is also effective except in homosexual men and during pregnancy.
- **Response to treatment** is considered as satisfactory, if there is a four-fold decrease in nontreponemal titers at 3–6 months in all stages of syphilis.
- **Neurosyphilis:** It should be followed up with lumbar puncture and evaluation of CSF every 6 months until the cell count is normal. If after 6 months the cell count is not decreased, retreatment should be given.

Treatment reactions

- **Anaphylaxis:** Penicillin is a common cause.
- **Jarisch–Herxheimer reaction:**
  - Treatment of syphilitic patients having a high bacterial load by antibiotics can cause a massive release of endotoxins, and cytokine causing Jarisch–Herxheimer reaction.
  - Jarisch–Herxheimer reaction is an acute febrile reaction that follows after (about 8 hours after the first injection) any therapy for syphilis. It is characterized by headache, myalgia, malaise, mild fever, rigors, and other symptoms that usually resolve within the first 24 hours.
  - It is common in early syphilis and rare in late syphilis.
  - It may induce fetal distress or premature labor in pregnancy. This concern should not prevent or delay therapy. It may be severe and worsen the clinical manifestations in cardiovascular or neurosyphilis.
  - Penicillin should not be withheld because of the Jarisch–Herxheimer reaction. Because, it is not dose dependent and there is no point in giving a smaller dose.
  - Prednisolone 10–20 mg orally three times daily for 3 days given for 24 hours prior to therapy may prevent the reaction.

TABLE 19.21: Management of syphilis.

Stage of syphilis	***Drug***	***Regimen***
Primary	Procaine penicillin	600,000 units IM/day for 12 days
	Oxytetracycline	500 mg orally four times/day for 15 days
	Doxycycline	100 mg orally two times/day for 15 days
	Benzathine penicillin	2.4 mega (million) units IM single dose (1.2 million units in each buttock)
Secondary	Procaine penicillin	600,000 units IM once daily for 15 days
	Benzathine penicillin	2.4 million units IM single dose
Early latent	Benzathine penicillin	2.4 million units IM single dose
Late latent/tertiary and cardiovascular syphilis	Benzathine penicillin	2.4 million units IM weekly for 3 weeks
Neurosyphilis	Crystalline penicillin	18–24 million units/day for 10–14 days
	Procaine penicillin PLUS probenecid	2.4 million units/day IM for 10–14 days + 500 mg QID for 10–14 days

(IM: intramuscular)

APPROACH TO A CASE OF GENITAL ULCER [GENITAL ULCER DISEASE (GUD)]

Definition: Genital ulcer is defined as ulcerative, erosive, pustular, or vesicular lesions on the genitalia with or without lymphadenopathy.

Etiology (Table 19.22)

TABLE 19.22: Causes of genital ulcer disease.

STD-related etiologies and organisms	
Genital herpes	*Herpes simplex virus type 1 and type 2*
Primary syphilis	*Treponema pallidum var. pallidum*
Chancroid	*Haemophilus ducreyi*
Lymphogranuloma venereum (LGV)	*Chlamydia trachomatis serovars L1-L3*
Granuloma inguinale (Donovanosis)	*Calymmatobacterium granulomatis* now called *Klebsiella granulomatis*

Contd...

Contd...

Non-STD-related etiologies	
Non-STD infectious	Candida, CMV, EBV, *Mycobacteria*, *Staphylococcus*
Noninfectious	Bechet's, Reiter's, cancer, trauma, aphthous, and fixed drug eruptions
No etiological agent is found in 20–50% of genital ulcer disease (GUD)	

(CMV: Cytomegalovirus; EBV: Epstein–Barr virus; STD: Sexually transmitted disease)

Features and differential diagnosis of genital ulcer disease are presented in **Table 19.23**.

TABLE 19.23: Differential diagnosis of a few genital ulcer diseases.

Characteristic	*Syphilis*	*Herpes (Fig. 19.38)*	*Chancroid*	*LGV*	*Donovanosis*
Primary lesion	Papule	Vesicle	Pustule	Papule, vesicle, and pustule	Papule
Number of lesions	Usually 1	Multiple	Multiple	Single	Variable
Diameter	5–15 mm	1–2 mm	Variable	2–10 mm	Variable
Edges	Sharply demarcated elevated	Erythematous and polycyclic	Undermined and ragged	Elevated, round, or oval	Elevated, irregular
Depth	Superficial or deep	Superficial	Excavated	Superficial or deep	Elevated
Base	Smooth and nonpurulent covered with serous exudate	Erythematous	Purulent and dirty gray base	Variable	Red velvety, bleeds easily
Induration	Button hole	None	Not indurated	Not indurated	Not indurated
Pain	Absent	Present	Present	Absent	Absent
Lymph nodes	Bilateral nontender, firm, lead shot, and nonsuppurative	Bilateral tender, firm, nonsuppurative	Unilateral, tender, suppurative, and unilocular	Unilateral, tender, suppurative, and multilocular	None pseudobubo seen

Q. DR10.9 **Describe the syndromic approach to ulcerative sexually transmitted diseases.**

Table 19.24 shows common sexually transmitted infection (STI) syndromes and their causative organisms.

TABLE 19.24: Common sexually transmitted infection (STI) syndromes and their causative organisms.

Kit	*Color*	*STI syndrome*	*Drugs*
1	Grey	Urethral discharge Cervical discharge Rectal discharge Painful scrotal swelling	Tablet azithromycin 1 g stat and tablet cefixime 400 mg stat
2	Green	Vaginal discharge	Tablet secnidazole 2 g stat and tablet fluconazole 150 mg stat
3	White	Genital ulcer, non-herpetic	Injection benzathine penicillin 2.4 mU IM stat and tablet azithromycin 1 g stat
4	Blue	Genital ucler, non-herpetic for patients allergic to penicillin	Capsule doxycycline 100 mg bd × 2 weeks and tablet azithromycin 1 g stat
5	Red	Genital ulcer, herpetic	Tablet acyclovir 400 mg tds × 7 days
6	Yellow	Lower abdominal pain	Tablet cefixime 400 mg stat, tablet metronidazole 400 mg bd × 2 weeks and capsule doxycycline 100 mg bd × 2 weeks
7	Black	Inguinal bubo	Capsule doxycycline 100 mg bd × 2 weeks and tablet azithromycin 1 g stat

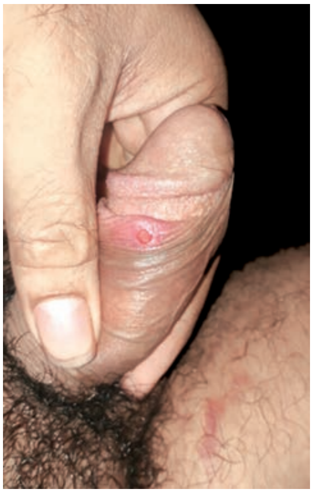


FIG. 19.38: Herpetic penile ulcer.

APPROACH TO VAGINAL DISCHARGE

Q. DR10.11 **Describe the etiology, diagnostic and clinical features and management of vaginal discharge.**

See **Flowchart 19.1**.

Dermatological Manifestations in HIV

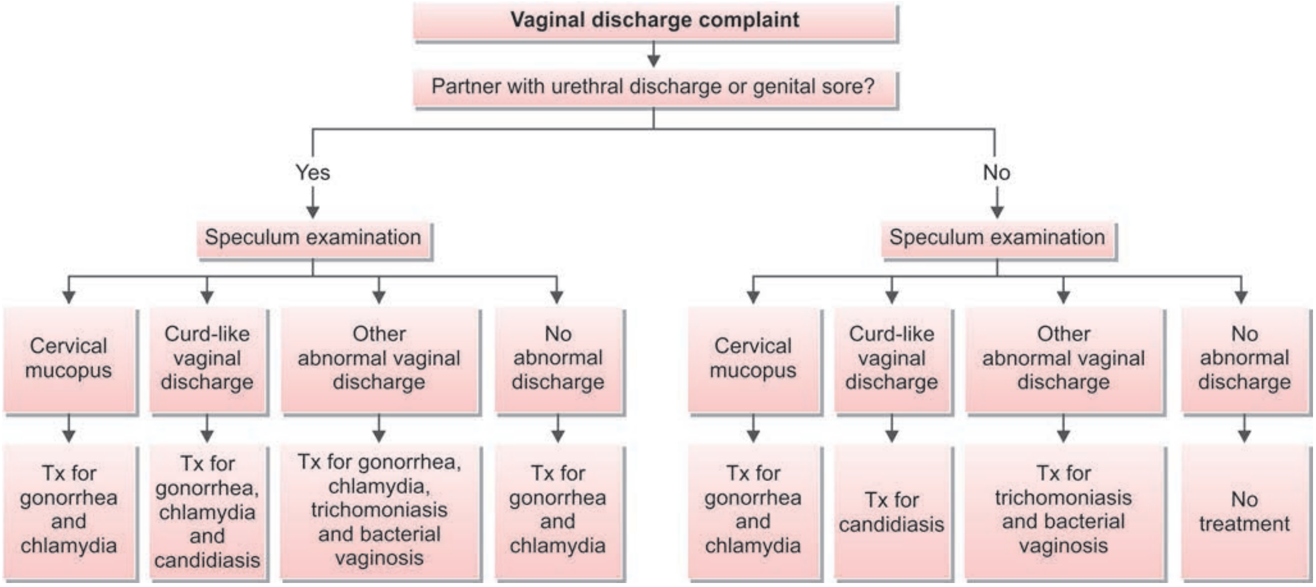
Q. DR11.1, 11.2, 11.3 **Name some dermatological manifestations in HIV.**

The dysregulation of CD4$^+$ lymphocytes and CD4$^+$ monocytic lineage leads to a variety of manifestations in HIV **(Table 19.25)**. However, ART in itself can induce complications.

Hence the dermatological manifestations in HIV are determined by:

- Evolving immunological state of the patient
- The specific viral characteristics of serotype
- Period of time from infection
- Length of antiretroviral treatment

FLOWCHART 19.1: Systematic management of vaginal discharge.



Vaginal discharge complaint
Partner with urethral discharge or genital sore?
Yes
No
Speculum examination
Speculum examination
Cervical mucopus
Curd-like vaginal discharge
Other abnormal vaginal discharge
No abnormal discharge
Cervical mucopus

TABLE 19.25: Cutaneous manifestations of HIV in relation to $CD4^+$ count.

$CD4^+$ T-cell count >500 cells/uL	***$CD4^+$ T-cell count 250–500 cells/uL***	***$CD4^+$ T-cell count <200 cells/UL***
Acute retroviral syndrome	Dermatophyte infections	Bacillary angiomatosis
Herpes zoster (nondisseminated)	Oral candidiasis	Hyperkeratotic scabies
Seborrheic dermatitis	Oral hairy leukoplakia	Cutaneous military tuberculosis
	Herpes zoster (disseminated)	Eosinophilic folliculitis
		➢ Herpes simplex virus infection (>1 month's duration) ➢ Idiopathic pruritus invasive fungal infection ➢ Kaposi sarcoma ➢ Molluscum contagiosum ➢ Popular eruption of HIV

Q. DR11.3 Medications and medication-related effects in the setting of HIV.

The HIV medications themselves can produce side effects as well as in the setting of HIV sulfonamides and penicillins can produce side effects. Antiretroviral medications themselves can cause adverse reactions like morbilliform, retinoid-like, vasculitic and bullous. Treatment includes supportive care, cessation of the etiological agent when necessary **(Table 19.26)**.

TABLE 19.26: Skin manifestations of antiretroviral agents.

Drugs	***Dermatological manifestations***
Nucleoside reverse transcription inhibitors (NRTIs)	Hypersensitivity, leukocytoclastic vasculitis, hyperpigmentation of palms, sole, nail bed, lipodystrophy, paronychia
Nonnucleoside reverse transcriptase inhibitors (NNRTIs)	Hypersensitivity, TEN (specific to nevirapine), lipodystrophy with rilpivirine
Protease inhibitor	Hypersensitivity, acute exanthematous pustulosis, dose dependent retinoid like effects
Fusion inhibitor	Systemic hypersensitivity reactions <1% of patients injection-site reactions upto 98% of patients
Integrase inhibitor	Pruritus, hypersensitivity (dolutegravir)

Infections in advanced HIV disease (opportunistic infections)

- Oral hairy leukoplakia
- Bacillary angiomatosis
- Mycobacterial infections
- Invasive mycoses
- Superficial mycoses
- Severe molluscum contagiosum
- Atypical leishmaniasis

Infections in well-controlled HIV

- Staphylococcal infection
- Herpes simplex virus 1 and 2 infections
- Varicella zoster infections
- Human papillomavirus infection
- Syphilis

Cutaneous malignancies in HIV

- Kaposi sarcoma **(Table 19.27)**
- Human papillomavirus-induced dysplasia and squamous cell carcinoma
- Cutaneous lymphomas in HIV

TABLE 19.27: HIV associated Kaposi sarcoma (KS) treatment according to WHO guidelines.

Mild/moderate as a disease	***Severe/symptomatic KS disease***
Immediate ART inhiation is recommended	Immediate ART initiation in combination with systemic chemotherapy
WHO definition of mild/moderate:	WHO definition of severe:
➢ Confined to skin and/or lymph nodes	➢ Symptomatic visceral disease
➢ No symptomatic visceral disease	➢ Extensive oral KS lesions which interfere with chewing or swallowing
➢ No significant oral disease	➢ Painful or disabling tumor-associated facial/genital/peripheral edema
➢ No edema affecting function	➢ Life-threatening or functionally disabling
➢ Not functionally disabling or life-threatening	➢ Progressive or persistent disease

Inflammatory cutaneous reactions in HIV

- Psoriasis
- Seborrheic dermatitis
- Popular pruritic eruption
- Eosinophilic folliculitis
- Immune reconstitution inflammatory syndrome (IRIS)

Q. Cutaneous manifestations of vitamin and mineral deficiency.

The deficiencies which will be highlighted here include vitamins A, C, E, and zinc.

MANIFESTATIONS OF VITAMIN A DEFICIENCY

Q. DR17.1 Enumerate and identify the cutaneous findings in vitamin A deficiency.

Fat-soluble Vitamins

Vitamin A (Box 19.31)

Vitamin A has both cutaneous and ocular manifestations. It is one of the most common causes of preventable childhood blindness in the world. It is also associated with deficiency in immune autoregulation. The RDA is 700 µg (adult females) and 900 µg (adult males).

Box 19.31: Cutaneous and ocular findings in vitamin A deficiency.

- ➢ Ocular
    - – Impaired dark adaption
    - – Xerophthalmia
    - – Corneal xerosis
    - – Keratomalacia
    - – Corneal perforation
    - – Blindness
- ➢ Cutaneous, mucocutaneous
    - – Xerosis
    - – Skin fissuring
    - – Phrynoderma
    - – Mucosa
    - – Xerostomia
    - – Hypotonia
    - – hypogeusia

Vitamin E (Tocopherol)

Vitamin E is rarely associated with deficiency or excess states of disease. Found in oils and shortenings, as well as various fortified grains, dark-green leafy vegetables, legumes, nuts, avocado, small fishes such as herring and sardines. Because it is a fat soluble vitamin excessive intake may augment effects of anticoagulant medications leading to purpura and hemorrhage. Severe spinocerebellar ataxia is usually a neurodegenerative disorder with AR inheritance. Patients with mutations in the α-tocopherol from lysosomes into lipoproteins that result in predisposition to oxidative stress in affected cells. The RDA is 15 mg/day.

Water-soluble Vitamins

Vitamin C

Q. DR17.3 Enumerate and describe the various changes in vitamin C deficiency.

The RDA is 90 mg (males) and 75 mg (females). Vitamin C is found in greatest concentration in pituitary, adrenal, liver, leukocytes and eyes. Depletion occurs after 1–3 months of deficient diet. **Table 19.28** lists the cutaneous, mucosal and systemic features of scurvy.

Zinc Deficiency

Q. DR17.4 Enumerate and describe the various changes in zinc deficiency.

Zinc deficiency occurs worldwide. Populations at special risk include patients with intestinal malabsorption syndromes liver disease, anorexia nervosa or food faddism, extracutaneous burns, and nephritic syndromes. Zinc deficiency may be either inherited, or secondary to impaired absorption, inadequate intake or excessive renal or intestinal losses. It may result in a clinical picture that resembles acrodermatitis enteropathica (AE) and occurs also in adults. This is also seen as a complication of bariatric surgery.

A chronic or subacute form has also been recognized. It manifests as growth retardation, hypogonadism in males, dysgeusia, poor appetite and poor wound healing.

AE, the inherited form of zinc deficiency, is a rare autosomal recessive disorder of zinc absorption. These infants have a defect in an intestinal zinc transporter, the human ZIP4 protein encoded on SCL39A4 gene.

Clinical Features of Acrodermatitis Enteropathica

- Eczematous and erosive dermatitis
- Preferentially localized to periorificial and acral areas
- Alopecia
- Diarrhea
- Lethargy, irritability
- Whining, crying
- Superinfection of *Candida* and *Staphylococcus aureus*.

Treatment

In children 0.5 mg—1.0 mg/kg of elemental iron is given as 1 or 2 daily divided doses. In adults 15—30 mg/day is the usual dose. Patients of acrodermatitis enteropathica need lifelong treatment.

TABLE 19.28: Cutaneous manifestations of Vitamin C deficiency.

Clinical manifestations of scury.	
Skin	➢ Follicular keratotic plugging ➢ Corkscrew hairs ➢ Perifollicular purpura ➢ Lower extremity of edema with ecchymosis ➢ Poor wound healing and dehiscence
Mucosa	➢ Swelling, ecchymoses, and bleeding of gingiva ➢ Hemorrhagic gingivitis, necrosis and loose of teeth
Other organs	➢ Hemorrhagic intra-articular, subperiosteal, intramuscular, disruption of growth plates, bowing of bones, depressed sternum ➢ Epistaxis, hematuria, gastrointestinal and cerebral hemorrhage

DIASCOPY

Diascopy or vitropression is a common office procedure where the application of pressure with help of a diascope usually a transparent glass slide will lead to alteration of the skin lesion, mostly used for the following purposes:

- In differentiating vascular from nonvascular lesions and observing for the blanching response in case of presence of vascularity in lesions such as telangiectasia, angioma, vascular tumors, and malformations.
- To differentiate purpura (due to extravasation of blood) due to vasculitis which does not blanch from reactive erythema due to other causes.
- For differentiating urticaria from cases of urticarial vasculitis which does not blanch.
- In differentiating nevus anemicus from nevus depigmentosus and vitiligo. The former lesions blanch and the edges are lost whereas the latter remains the same.
- It can be used for the demonstration of apple jelly nodules which are yellowish-brown nodules seen on diascopy seen classically in lupus vulgaris but also in cases of lupoid leishmaniasis, lupoid rosacea, sarcoidosis, granuloma faciale, and pseudolymphoma.
- It can be used for making the hypopigmented macules of the lip prominent and also for differentiating macules of vitiligo which appears uniform white with convex margins from that of postinflammatory hypopigmentation which appears tan-brown with uneven or jagged margins.
- It can be used for assessing the vascularity of lesions before a biopsy or surgical excision.
- It can make the lesions look more prominent in lichen planus, lichen sclerosus et atrophicus, and seborrheic keratosis.
- In the case of xanthelasma like conditions, it can make the yellow color more prominent, such as xanthomas, necrobiosis lipoidica, and pseudoxanthoma elasticum.

20

CHAPTER

Psychiatry

Classificatory Systems in Psychiatry

	ICD-11: International Classification of Diseases	*DSM-5: Diagnostic and Statistical Manual*
Published by	WHO in 2018	American Psychiatric Association in 2013
Disorders included	All medical disorders in 26 chapters Psychiatric disorders classified in Chapter 6 of ICD	Psychiatric disorders only

Q. PS3.2 Enumerate, describe and discuss important signs and symptoms of common mental disorders.

Mental Status Examination (Systemic Examination in Psychiatry)

It involves the following areas:

General Appearance and Behavior

- Grooming: Note whether the patient is well-groomed or has poor hygiene [e.g., overdressed for the occasion/unkempt
- Posture (e.g., drooping of shoulders)]
- Facial expressions [e.g., happy, sad, *Otto Veraguth sign* (increased forehead marking seen in depression), worried, excess perspiration, and tensed voice (signs of anxiety)]
- Eye to eye contact made or not
- Attitude towards examiner (e.g., cooperative/hostile/agitated)
- Psychomotor activity: Motor execution of psychic events (e.g., restlessness/retardation)

Speech

Assess fluency, speed, volume, and tone (e.g., slow and low tone speech in depression, excessive and high tone speech in mania)

Thought Abnormalities

- **Thought formation—**Is the speech coherent? Or is there loosening of association? (Suggests schizophrenia)
- **Thought possession—**Ask the patient if the thoughts are his own or if it is controlled by an external source. It can be:
  - *Thought insertion*—Someone else's thoughts are being put in one's mind.
  - *Thought withdrawal*—One's thoughts are being removed from one's mind.
  - *Thought broadcast*—Many people are getting to know one's thoughts.
- **Thought stream—**Speed: increased (flight of ideas), decreased (inhibition, slowing of thinking).
- **Thought continuity—**Perseveration (repetition beyond the point of relevance), thought block.
- **Thought content—**Determined by asking "What are your main concerns?" Look for presence of ***delusions, obsessions***.

Delusion

Q. FM5.2 Define, classify and describe delusions, hallucinations, illusion, lucid interval and obsessions with exemplification.

It is a false belief held with strong conviction despite superior evidence to the contrary (strongly held false beliefs). It is a disorder of thought content.

Types of Delusion

- **Persecutory** (e.g., belief that others are out to harm me)
- **Grandiose** [e.g., belief that one has special powers or status (suggests mania)]

- **Nihilistic** (e.g., conviction that "My head is missing", "I have no body", "I am dead")
- **Erotomanic** delusion (e.g., believing a movie star secretly loves them)
- **Somatic** delusion (e.g., believing head is filled with air/worms-parasitosis)
- Delusion of **reference** (e.g., belief that the story in a book is referring to them)
- Delusion of **control/passivity** (e.g., believing one's thoughts and movements are controlled by aliens).
- Other delusions are delusion of jealousy/infidelity/guilt/misinterpretation/parasitosis, hypochondriacal delusion, fantastic/bizarre delusion

In contrast, ***overvalued ideas*** are strongly held but not fixed.

Obsessions

These are persistent, recurrent, unwanted thoughts/ideas/impulses/images that seem to invade a person's consciousness and hence cause marked anxiety/distress. Theme of obsessions can be of following types:

- *Cleanliness:* Fears of contamination
- *Symmetry and numbers:* Reading the same line for a particular number of times
- *Forbidden or taboo thoughts:* Aggressive, sexual, and religious obsessions
- *Harm* (e.g., thoughts about harm on oneself or others)

Mood and Affect

- **Mood** *(subjective longitudinal emotional state):* Ask the patient how he feels (e.g., sad/happy/anxious/tensed/worried)
- **Affect** *(objective cross-sectional emotional state)* is assessed by observing facial expression, posture, movements [(e.g., depressed/elated/anhedonic) (inability to experience pressure from previously pleasurable activities)]
- Elevated mood with excess energy and reduced need for sleep (suggests mania)
    - Feeling guilty or hopeless (suggests depression). Note whether patient has thoughts of self-harm? If so, enquire about plans
    - Feeling excessively worried about many things (suggests anxiety).

Perceptual Abnormalities

Assess for presence of hallucination or illusion.

Hallucination

- It is perception in the absence of corresponding external stimuli (i.e., sensory experiences of stimuli that is not actually present). It is a disorder of thought perception.
- It can occur in any sensory modality; most common in psychiatric disorders being *auditory* (thought echo, command hallucination, running commentary) and most common in organic psychiatric disorders being *visual* (e.g., seeing "visions", Lilliputian hallucination).
- Other types include *tactile* (cocaine bug); superficial/kinesthetic/visceral, olfactory, gustatory, and complex hallucinations.
- In narcolepsy two specific hallucinations are seen.
    - *Hypnagogic*: They occur when falling asleep
    - *Hypnopompic*: They occur on waking

  Table 20.1 shows the differences between true perception, hallucination, and mental imagery.

TABLE 20.1: Differences between true perception, hallucination, and mental imagery.

	Source of stimuli	*Individual's awareness of source of stimuli*
True perception	Comes from external world	Realizes as coming from outside
True hallucination	Comes from within (one's own mind)	Considers it real and as coming from external world
Mental imagery	Comes from within	Realizes as coming from within

Pseudohallucination: Phenomenon lying in between true hallucination and mental imagery

- Hare described it as hallucination with insight
- Jasper described it as hallucination occurring in inner subjective space
- Kandensky described it as mental imagery that is clear

In contrast, **illusions** are misperceptions of real external stimuli (e.g., mistaking a shrub for a person in poor light)

Lucid interval (LI) is the period of time between regaining consciousness after a short period of unconsciousness, resulting from a head injury and deteriorating after the onset of neurologic signs and symptoms caused by that injury.

Q. PS3.3 Elicit, present and document a history in patients presenting with a mental disorder.

TABLE 20.2: Abnormalities of consciousness.

Quantitative	*Qualitative*
➢ Clouding	➢ Twilight: Disruption of continuity
➢ Drowsy: Drifts to sleep if not actively stimulated	➢ Oneiroid: Dream-like state
➢ Sopor/obtundation: Constant stimulation even for minimal response	➢ Stupor: Akinesia + mutism in awake, alert patient
➢ Coma: Complete unawareness, cannot be aroused	➢ Delirium: Altered sensorium

Cognitive Functions

- ***Level of consciousness and alertness*:** Important in case of delirium (**Table 20.2**)
  Normal consciousness: Alert, vigilant, and lucid
- ***Orientation to time, place, and person*** (e.g., ask what time is it? Where are you now? Ability to recognize family members)
- ***Attention and concentration:*** It is assessed by serial subtraction test (100 – 7) in which the patient is asked to subtract 7 from 100 and then 7 from the answer and so on.
- ***Memory:*** Assessed based on length of storage of memory
  - ***Registration/Immediate:*** It is judged by asking the patient to repeat simple new information (e.g., name and address) **immediately** after hearing it. It is dependent on attention and concentration.
  - ***Recent:*** It is judged by asking the patient to repeat simple new information (as mentioned above) **after an interval of 1–2 minutes** during which time the patient's attention should be diverted elsewhere **or 24 hours recall.**
  - ***Remote:*** It is judged by asking the patient to recall past events (>24 hours).
- ***Intellectual Ability:*** It can be assessed by asking about general knowledge, calculation, and vocabulary.
- ***Abstract Ability:*** It can be assessed using similarity test (e.g., What is the similarity between chair and table) and proverb test (ability to understand inner meaning of a proverb).
- ***Judgment:*** It can be assessed by giving a certain test situation and asking how would the patient respond (e.g., What would you do if you found an addressed letter on road).
- ***Insight***: It refers to patients understanding of one's illness, its cause, and the need for treatment. Lack of insight (i.e., failure to accept that one is ill and/or in need of treatment and is a feature of psychotic disorders). Grading of insight described in color box.

Grading of Insight

- Grade a: Complete denial of illness
- Grade b: Slight awareness of being ill and needing help, but denying it at the same time
- Grade c: Aware of being ill, but blaming it on others, external factors or on organic factors
- Grade d: Aware of being ill, but attributing it to internal unknown factors
- Grade e: Intellectual insight—aware of being ill and that the symptoms are due to disturbance in thoughts/feelings/behavior but unable to apply this knowledge to current/future experiences
- Grade f: True emotional insight—aware of being ill and that the symptoms are due to disturbance in thoughts/feelings/behavior and also is able to apply this knowledge to bring about changes in behavior.

Q. PS3.5 Perform, demonstrate and document a mini-mental examination.

Table 20.3 shows the mini-mental state examination.

TABLE 20.3: Mini-mental state examination.

Component assessed	*Test score/ total score*
1. Orientation:	
Time: Day, date, month, year	-/5
Place: Room/floor/building, city, district, state, country	-/5
2. Registration: Examiner presents three names of unrelated objects that the patient is asked to repeat immediately (e.g., apple, Sunday, blue)	-/3
3. Attention and calculation *Serial subtraction* of 7 from the answer starting from 100, to continue up to five steps (e.g., 93, 84, 77, 70, 63) OR Spell *WORLD backwards* (e.g., DLROW)	-/5
4. Recall: Patient is asked to recall the three words given during registration assessment	-/3
5. Language:	
a. *Naming* any two objects (e.g., book and table)	-/2
b. *Repeat the sentence* "No, ifs, ands or buts"	-/1
c. *Follow a three stage command* (e.g., "Pick the paper from table, crumble it and throw in the dustbin")	-/3 -/1
d. *Read and obey the command* (e.g., "Close your eyes")	-/1
e. *Writing a sentence*	
6. Copy an *intersecting pentagon*	-/1
Final Score	-/30
MMSE Scoring ➢ ≥24: No cognitive impairment ➢ 18–23: Mild cognitive impairment ➢ ≤17: Severe cognitive impairment	

PSYCHOPHARMACOLOGY

Q. PS18.1 **Enumerate the indications and describe the pharmacology, dose and side effects of commonly use drugs in psychiatric disorders.**

Drugs used in psychiatry:

- Antipsychotics: For psychosis
- Antidepressants: For depression
- Mood stabilizers: For bipolar affective disorders
- Antianxiety drugs: For anxiety disorders

ANTIPSYCHOTIC DRUGS

Classification of Antipsychotic Drugs (Table 20.4)

Typical antipsychotics/first generation:

- Phenothiazines (chlorpromazine, perphenazine, fluphenazine, and thioridazine)
- Thioxanthenes (flupentixol and zuclopenthixol)
- Butyrophenones (haloperidol and droperidol)

Atypical antipsychotics/second generation:

- Aripiprazole, asenapine, brexpiprazole, cariprazine, clozapine, iloperidone, lurasidone, olanzapine, paliperidone, pimavanserin, quetiapine, risperidone, and ziprasidone

Mechanism of action of most first- and second-generation antipsychotics: It appears to be postsynaptic blockade of brain dopamine D2 receptors. ***Exceptions:***

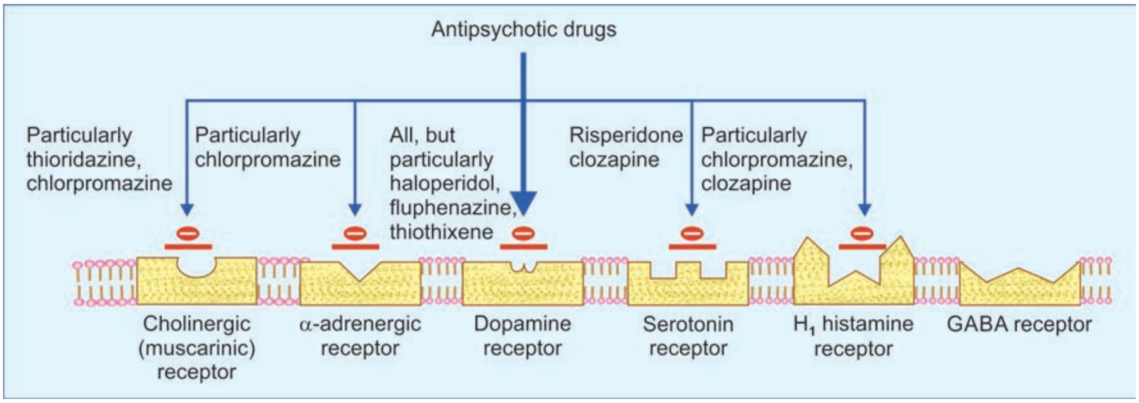
- Aripiprazole and brexpiprazole are D2 receptor partial agonists
    - Cariprazine is a D3-preferring D3/D2 receptor partial agonist
    - Pimavanserin is a serotonin 5HT2A inverse agonist and antagonist with no dopamine D2 affinity

TABLE 20.4: Differences between typical and atypical neuroleptic drugs.

	Typical neuroleptic	***Atypical neuroleptic***
Mode of action	D2 antagonist	5-HT2A antagonist D2 antagonist + Rapid D2 dissociation
Other effect	Antagonism of H1, M1, alpha-1 receptor, among other	Antagonism of H1, M1, 5-HT2c, alpha-1 receptor, among other
Effect on schizophrenia symptoms	Improvement in positive symptoms	Improvement in both positive and negative symptoms
EPS, TD, hyperprolactinemia	Pronounced	Less
Metabolic side effects	Few	Marked
Mood stabilizing property	Less	More

(EPS: Extrapyramidal symptoms; TD: Tardive dyskinesia)

Antipsychotic Drugs and their Action (Fig. 20.1)



Antipsychotic drugs
Particularly thioridazine, chlorpromazine
Particularly chlorpromazine
All, but particularly haloperidol, fluphenazine, thiothixene
Risperidone clozapine
Particularly chlorpromazine, clozapine
Cholinergic (muscarinic) receptor
α-adrenergic receptor
Dopamine receptor
Serotonin receptor
H_1 histamine receptor
GABA receptor

FIG. 20.1: Antipsychotic drugs and their action.

Indications

- **Psychomotor agitation:** High-potency APMs (haloperidol) parenteral.
- **Schizophrenia:** Treatment of choice for acute psychotic episodes and for prophylaxis
- **Other psychotic disorders:** Treatment of psychotic disorders due to general medical conditions and substances, delusional disorder, brief psychotic disorder, schizophreniform disorder, and other rarer psychotic disorders.
- **Mood disorders:** Treatment of agitation and psychosis during mood episodes.
- **Sedation:** Useful when benzodiazepines are contraindicated (especially in older patients) or as an adjunct during anesthesia.
- **Movement disorders:** Treatment of choice for Huntington disease and Tourette disorder.

General Adverse Effects

- **Sedation:** Due to the antihistaminic activity.
- **Hypotension:** Effect is due to alpha-adrenergic blockade and is most common with low potency antipsychotic medications.
- **Anticholinergic symptoms:** Dry mouth, blurred vision, urinary hesitancy, constipation, bradycardia, confusion, and delirium.
- **Endocrine effects:** Gynecomastia, galactorrhea, and amenorrhea (secondary to hyperprolactinemia).
- **Dermal and ocular syndromes:** Photosensitivity, abnormal pigmentation, and cataracts. Thioridazine can cause retinitis pigmentosa.
- **Cardiac conduction abnormalities:** Ziprasidone prolongs QT interval.
- **Agranulocytosis:** Clozapine
- **Movement syndromes:** Tardive dyskinesia (TD)
- **Extrapyramidal syndromes (EPS):** Newer APMs cause minimal or no EPS. Low-potency APMs (e.g., chlorpromazine, thioridazine) cause less EPS than higher-potency APMs, but has more sedative effects.
- **Metabolic syndrome:** Weight gain, diabetes, and dyslipidemia
- **Cholestatic jaundice**
- **Neuroleptic malignant syndrome**

ANTIDEPRESSANTS

Table 20.5 shows the various types of antidepressants and their side effects.

TABLE 20.5: Various types of antidepressants and their side effects.

Group and drug	*Side effects*
Monoamine oxidase (MAO) inhibitors ➢ ***Irreversible inhibitors of MAO-A and B:*** Isocarboxazid, phenelzine, tranylcypromine ➢ ***Reversible inhibitor of MAO-A (RIMA)s:*** Moclobemide and clorgyline	➢ ↑Appetite (phenelzine) ➢ ↓Appetite (tranylcypromine) ➢ Hepatotoxicity, SLE, drug, and food interactions (cheese reaction)
Tricyclic antidepressants (TCAs) ➢ ***NA + 5 HT reuptake inhibitor:*** Amitriptyline, imipramine, trimipramine, clomipramine, doxepin, dothiepin, and dosulepin ➢ ***Predominantly NA reuptake inhibitor:*** Desipramine, nortriptyline, amoxapine, reboxetine	➢ Anticholinergic: Dry mouth, bad taste, constipation, epigastric fullness, urinary retention (more common in elderly male), blurred vision, and palpitation ➢ Sedation, mental confusion, and weakness ➢ Increased appetite and weight, sweating, fine tremors, precipitation of seizures, postural hypotension, cardiac arrhythmias, rashes, and jaundice
Selective serotonin reuptake inhibitors (SSRIs) ➢ Fluoxetine, fluvoxamine, paroxetine, sertraline, citalopram, and escitalopram	➢ GI upset, nausea, interfere with ejaculation, nervousness, restlessness, insomnia, anorexia, headache, diarrhea, epistaxis, ecchymosis, and serotonin syndrome
Selective norepinephrine reuptake inhibitors (SNRIs): Duloxetine, venlafaxine	➢ Hypertension
Atypical antidepressants ➢ Trazodone, mianserine, mirtazapine, tianeptine, amineptine, and bupropion	➢ Priapism (trazodone), bone marrow suppression, hepatotoxicity
NMDA (glutamate) antagonists: Ketamine	➢ Psychosis

Serotonin Syndrome

- Life-threatening conditions associated with increased serotonergic activity in the central nervous system most often due to SSRI overdose.
- Symptoms are diaphoresis, tachycardia, hyperthermia, hypertension, vomiting, diarrhea, tremor, muscle rigidity, myoclonus, hyperreflexia, and bilateral Babinski sign.
- Treatment involves stopping of all serotonergic agents, supportive care to normalize vital signs, hyperthermia and autonomic instability, sedation with benzodiazepines, and administration of serotonin antagonists (Cyproheptadine).

Cheese Reaction

- Cheese, beer, wine, meat, fish, yeast (contain large amount of tyramine and other indirectly acting amines) → these escape degradation in intestinal wall and liver due to irreversible block of MAO → reach to circulation and displace large amount of noradrenaline from loaded nerves → hypertensive crises (CVA, encephalopathy)
- Treatment: IV phentolamine, prazosin

If antidepressants are given for bipolar depression, they should be combined with a mood-stabilizing drug (mentioned below) to avoid "switching" the patients into (hypo) mania.

MOOD-STABILIZING AGENTS

They help in bringing the mood back to normal. The main drugs consist of lithium, sodium valproate, divalproex, and carbamazepine. Others include lamotrigine, gabapentin, topiramate, olanzapine, quetiapine, and risperidone.

Lithium (Lithium Carbonate)

Indications

- It is the first-line medication for the treatment of euphoric mania.
- It is used for both treatment and prophylaxis of mood episodes in bipolar affective disorder.
- Adjunctive treatment of resistant depression in combination with tricyclic antidepressants.
- Treatment of schizoaffective disorders.
- It has antisuicidal properties.
- Other uses: Cluster headache, gout, ulcerative colitis, and neutropenia.

Mechanism of action

- Lithium partly replaces sodium and is nearly equally distributed in and outside the cell: This affects ionic fluxes across the brain cells.
- It decreases the release of NA and DA without affecting 5 HT release.
- It inhibits hydrolysis of inositol monophosphate.

It has a narrow therapeutic range. Hence, a regular blood monitoring is needed to maintain a plasma level of **0.6–1.2 mmol/L.**

Side effects

- **Dose-related: Tremor, convulsions,** gastrointestinal distress (nausea, vomiting), and headache.
- **Acne and weight gain:** Long-term use may result in weight gain, interfere with patient compliance and exacerbate psoriasis.
- **Cardiac conduction:** Prolonged **QRS, heart blocks, T wave inversions,** and ECG changes usually benign.
- **Hypothyroidism, nephrogenic diabetes insipidus,** increased calcium and parathormone, and renal failure.
- Teratogenicity: Associated with **Ebstein's anomaly**, and should not be given during the first trimester of pregnancy.
- Leukocytosis: Usually occurs and seems to be benign.

Divalproex

- Treatment of choice for rapid-cycling bipolar disorder, or when lithium cannot be used.
- Time course of treatment response is similar to lithium.
- **Side effects:** Sedation, cognitive impairment, tremor, GI distress, and hepatotoxicity.
- **Teratogenicity:** Associated with **spina bifida**.

Carbamazepine

- Second-line choice for treatment of bipolar disorder when **Lithium** and **Divalproex** are ineffective or contraindicated.
- **Side effects: Agranulocytosis** hematologic toxicity, hyponatremia, and hepatotoxicity.

Gabapentin

This lipophilic GABA derivative crosses to the blood brain-barrier and enhances GABA release but does not act as agonist at GABA receptor. It is used primarily to treat focal seizures and neuropathic pain, and can also be used for bipolar disorders.

Sodium Valproate and Olanzapine

- They can be used both as prophylaxis in bipolar disorder, and as second-line alternative to lithium.
- **Side effects:** Valproate can cause birth defects and, hence, should not be given to women of child-bearing age. Olanzapine can produce weight gain.

ANXIOLYTIC (ANTIANXIETY) MEDICATIONS (TABLE 20.6)

TABLE 20.6: Antianxiety drugs.

Benzodiazepine	*Azapirones*	*Others*
➢ Clonazepam ➢ Alprazolam ➢ Lorazepam ➢ Nitrazepam ➢ Diazepam ➢ Oxazepam ➢ Chlordiazepoxide	➢ Buspirone ➢ Gepirone ➢ Ipsapirone	➢ Beta blocker: Propranolol ➢ Antihistaminics: Hydroxyzine ➢ SSRIs and other antidepressant drugs

Indications for anxiolytic (antianxiety) medications:
- Panic disorder: Alprazolam, SSRIs, imipramine, and clonazepam decrease frequency and intensity
- Generalized anxiety disorder: Venlafaxine, other SSRIs, and buspirone decrease overall anxiety
- Social phobia: SSRIs and buspirone decrease fear associated with social situations
- Adjustment disorder with anxious mood: Benzodiazepines with supportive psychotherapy
- Obsessive compulsive disorder: SSRIs and clomipramine decrease obsession thinking

Features of Benzodiazepines:
- Mechanism: Bind to specific CNS receptors that modulate **GABA** transmission
- Commonly used for the treatment of anxiety, insomnia, and for alcohol withdrawal symptoms
- First choice for **emergency treatment of acute anxiety and severe mania**
- **Alprazolam** is the first choice for **panic attack**
- **Chlordiazepoxide** is used for prevention of **alcohol withdrawal**
- Benzodiazepines that do not interact with **P450: lorazepam**, **oxazepam,** and **temazepam**
- **Zolpidem:** Used in initial insomnia-t ½ 2–3 hours. Side effects include headache, nausea, dry mouth, etc.
- **Zopiclone:** Also acts on GABA receptors, and has short duration of action
- **Suredone, bretazenil, imidazenil, alpidem, and abecarnil:** Anxiolytic as well as anticonvulsant

Adverse effects:
- Sedation, disinhibition, tolerance, withdrawal, abuse potential, and possible teratogenicity
- Impairment of cognitive and motor performance

Features of Buspirone:
- It is used for the treatment of generalized anxiety disorder and social phobia
- Lag time of about **1 week** before clinical response
- **No additive effect** with **alcohol** or **sedative-hypnotics**
- No withdrawal syndrome
- No sedation or cognitive impairment
- Headache may occur

ELECTROCONVULSIVE THERAPY

Q. Describe modified electroconvulsive therapy and enumerate its indications.

Q. PS18.2 Enumerate the indications for modified electroconvulsive therapy.

Electroconvulsive therapy (ECT) is a procedure in which electrical stimuli is used to induce seizures.

Procedure for Modern ECT

- Obtain written informed consent
- Preanesthetic work-up
- Withholding drugs that can raise seizure threshold, NPO for 12 hours prior to procedure
- Premedication with anticholinergics to decrease secretions
- Administration of muscle relaxant (to prevent trauma to muscles and bones) and short-acting anesthetic agent
- **Electrode placement:** Electrodes are placed at the temporal fossa, 2.5–4 cm (1–1.5 inches) above the line joining the tragus of the ear and the lateral canthus of the eye.
- A brief electrical stimulus is delivered and seizure activity is noted mechanically via isolated limb and electrically via EEG.

Types of electroconvulsive therapy (ECT):
- **Direct:** ECT without general anesthesia which has been prohibited and hence not practiced
- **Modified:** Use general anesthesia and muscle relaxants
- **Unilateral ECT:** Right unilateral (RUL) has less cognitive effect, may be less clinically effective
- **Bilateral ECT:** Most common, most effective, most cognitive dysfunction

Mechanism of Action

Alteration in levels of neurotransmitters, neuromodulators [e.g., increase in brain-derived natriuretic factor (BDNF)].

Indications

- **Severe depression:** When a rapid antidepressant response is needed (e.g., due to failure to eat or drink in depressive stupor; high suicide risk), previous history of good response to ECT, patient preference, and suicidal ideas.

- **Failure to respond to drug treatments** or patient is not able to tolerate side effects of drugs (e.g., puerperal depressive disorder or postpartum psychosis).
- **Catatonic schizophrenia**
- **Resistant OCD**
- **Neuroleptic malignant syndrome**
- **Intractable seizure**
- **Parkinson's disease (rigidity, bradykinesia)**

Contraindications

- **Absolute:** None
- **Relative:**
  - Increased intracranial pressure (ICP)
  - Cardiovascular diseases: Recent MI, coronary artery disease, hypertension, aneurysms, and arrhythmias
  - Cerebrovascular disease: Recent strokes, space-occupying lesions, and aneurysms
  - Severe pulmonary diseases: Tuberculosis, pneumonia, and asthma
  - Deep vein thrombosis (DVT)
  - High risk pregnancy
- **Risks and side effects:** ECT is safe with few side effects.
  - Impairment of cognition: Period of confusion immediately after ECT and generally lasts for few minutes to several hours.
  - Memory loss: May forget weeks/months before treatment, during treatment, or after treatment has stopped. Usually improves within a couple of months. Permanent loss of memory is rare.
  - Myalgia, dislocation, and fractures
  - Medical complications: Nausea, vomiting, headache, aspiration, and jaw pain.

Q. PS18.3 **Enumerate and describe the principles and role of psychosocial interventions in psychiatric illness.**

PSYCHOTHERAPY

It mainly can be classified into three types:

Supportive

- It focusses on enhancing stress coping mechanisms and strengthening defenses to bring about emotional equilibrium.
- There is no cause finding or an intent to change the personality.
- It is used in the management of adjustment disorder.

Reconstructive

- It focuses on finding out the root cause of a problem in personality and attempts at personality reconstruction.
- Based on Sigmund Freud's principles of psychoanalysis: Making the patient aware of repressed unconscious conflicts, teaching them skills for better personality development
- Classical psychoanalysis and brief psychodynamic therapy are the two types
- It is less commonly used in the current days.

Re-educative

- It focusses on modifying patients' thinking (cognitive), behavior or both (combined)
- It aims at restructuring cognitive distortions with no much emphasis on cause finding and has been given specific names based on methods used, such as:
  - ***Systematic desensitization*** in phobia and OCD where in systematic exposure to phobic stimuli is done followed by use of relaxation techniques to desensitize the patient. It is based on the principle of exposure decreases fear and avoidance increases fear.
  - ***Graded exposure and response prevention*** in phobia and OCD: It is similar to systematic desensitization; however, no relaxation techniques are used.
  - ***Cognitive behavior therapy*** for depression wherein negative schemas, cognitive distortions seven automatic thoughts are addressed.
  - ***Eye-movement desensitization reprocessing*** is used for PTSD.
  - ***Aversive therapy*** used in paraphilias, wherein aversive stimuli is applied to decrease the undesired behavior.

CLINICAL PSYCHIATRY: APPROACH TO DIAGNOSIS IN PSYCHIATRY

Q. PS3.12 Describe, discuss and distinguish psychotic and nonpsychotic disorders (Table 20.7).

TABLE 20.7: Differentiating between psychosis and neurosis.

	Psychosis	*Neurosis*
Insight/Reality contact/Illness awareness	Absent	Present
Delusions/hallucinations	Present	Absent
Neurotransmitter involved	Dopamine	Serotonin
Pharmacotherapy of choice	Antipsychotics	Selective serotonin reuptake inhibitor
Interpersonal behavior	Marked disturbance	Preserved
Empathy	Absent	Present
Examples	Schizophrenia	Anxiety, phobia, depression

PSYCHOSIS (FIG. 20.2)

- Psychosis is a symptom or feature of mental illness characterized by radical changes in personality, impaired functioning, and thoughts that are distorted or nonexistent.
- It is an abnormal condition of the mind described as involving a **'loss of contact with reality'**.
- Psychosis is not pathognomonic of psychiatric disorder. It is a nonspecific cluster of signs and symptoms that may occur in medical, neurologic, and surgical disorders or as a consequence of pharmacologic treatment, substance abuse, or the withdrawal of drugs and alcohol.
- **Classification of psychoses:** Organic or functional **(Table 20.8)**:
  - **Organic psychotic disorders** are caused by structural defects or physiologic dysfunction of the brain (e.g., brain tumor).
  - **Functional disorders** have no identifiable cause (e.g., schizophrenia or bipolar disorder).
- **Lack of insight** refers to failure to accept that one is ill and/or in need of treatment and is characteristic of acute psychosis.
- Specific psychotic symptoms include delusions, hallucinations, ideas of reference, and disorders of thought.

Functional psychosis can be affective or nonaffective **(Table 20.9)**. **Table 20.10** shows the differences between schizophrenia and delusional disorders.

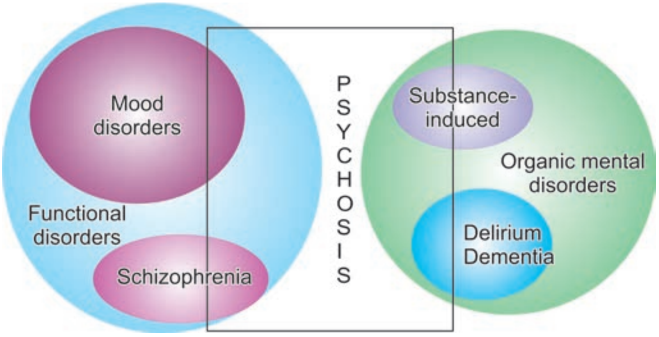


FIG. 20.2: Relationship of various psychological disorders.

TABLE 20.8: Differentiating between functional and organic psychosis.

	Functional psychosis	*Organic psychosis*
Demonstrable underlying **cause**	Absent	Present
Predominant type of **hallucination**	Auditory	Visual
Sensorium	Intact	Altered
Onset	Gradual	Acute
Focal neurological deficit	Usually absent	Usually present
Example	Schizophrenia	Delirium

TABLE 20.9: Differences between nonaffective and affective psychosis.

	Nonaffective psychosis	*Affective psychosis*
Mood symptoms	Not predominant	Predominant
Includes	➢ Schizophrenia ➢ Delusional disorder	➢ Bipolar disorder ➢ Schizoaffective disorder

TABLE 20.10: Differentiating between schizophrenia and delusional disorder.

	Schizophrenia	*Delusional disorder*
Delusions	Present	Present
Hallucinations	Present	Absent
Behavior	Abnormal	Normal
Socio-occupational functioning	Impaired	Intact

Affective psychosis can be further differentiated as **(Table 20.11)**:

TABLE 20.11: Differences between bipolar and schizophreniform disorders.

	Bipolar disorder	*Schizophreniform disorder*
Episodes	Mania/depression ± Psychosis (Psychotic symptoms; delusions are usually mood congruent)	Mania/depression + Psychosis
Intervening period	Normal	Psychotic symptoms always present

Q. PS5.1 Classify and describe etiology, clinical features and management of schizophrenia.

Schizophrenia was also called as:

- Demence precoce: Benedict Morel
- Dementia praecox: Emil Kraepelin
- Eugen Bleuler coined the term schizophrenia
- Schizophrenia is a disorder characterized by perturbations of language, perception, thinking, social activity, affect, and volition.
- Schizophrenia occurs with regular frequency nearly everywhere in the world in **1% of population** and begins mainly in young age (mostly around 16–25 years).
- Schizophrenia has a 10% suicide rate (approximately one-third attempt suicide).

Etiology of Schizophrenia

- **Genetic:** Schizophrenia has a high genetic predisposition, involving many susceptibility genes [e.g., disrupted in schizophrenia (DISC-1), neuregulin (NRG-1), and 22q deletion].
- **Biochemical:**
  - Dopamine: ↑ in mesolimbic (+ve symptoms), ↓ in mesocortical (–ve symptoms)
  - Serotonin increase: Responsible for +ve and –ve symptoms
  - Norepinephrine decrease: Responsible for –ve symptoms
- **Neuropathological:** ↑ size of ventricles, ↓ size of limbic system, basal ganglia
- **Environmental:** Maternal exposure to infection (influenza, rubella), advanced paternal age, winter birth, urban birth and upbringing, stressful life events, cannabis use, obstetric complications, and developmental abnormalities.
- **Abnormal family dynamics:** Negative expressed emotions in family lead to early relapse.
- **Psychological stresses:** Episodes of acute schizophrenia may be precipitated by social stress, adverse life events, and cannabis (which increase dopamine turnover and sensitivity).
- ***Schizophrenia syndrome:*** It is characterized by temporal lobe epilepsy, Huntington's chorea, cerebral tumors, and demyelinating diseases. This is known as **symptomatic schizophrenia**.

Clinical Features of Schizophrenia

DSM-5 diagnostic criteria for schizophrenia: Patient must have at least two of five symptoms for 6 months, with at least 1-month of active symptoms.

Table 20.12 shows the positive and negative symptoms of schizophrenia.

TABLE 20.12: Positive and negative symptoms of schizophrenia.

Positive symptoms	*Negative symptoms*
➢ **Delusions** ➢ **Hallucinations** ➢ **Disorganized/bizarre behavior:** Aggressive/agitated, odd clothing or appearance, odd social behavior, and repetitive stereotyped behavior ➢ **Disorganized thought/speech:** Loosening of association, formal thought disorders, neologisms, and conceptual disorganization	➢ **Alogia:** "Lack of words," including poverty of speech and of speech content in response to a question ➢ **Affective flattening/blunting:** Lack of expressive gestures ➢ **Alexithymia:** Inability to describe and express emotions ➢ **Avolition:** Loss of drive ➢ **Apathy:** Lack of concern ➢ **Anhedonia:** Loss of interest in previously pleasurable activities ➢ **Asociality:** Diminished social engagement, few friends, activities, interests; impaired intimacy ➢ **Attention impairment**

Eugen Bleuler's Criteria for the Diagnosis of Schizophrenia

Eugene Bleuler's 4A's/primary symptoms of schizophrenia:

1. **Autism:** Self-absorbed, totally engrossed in own thoughts, not concerned of external stimuli
2. **Association loosening:** Loss of logical sequence of thought, disconnected thoughts
3. **Ambivalence:** Inability to choose between two opposite *thoughts* (Ambitendency: Inability to choose between two opposite *action,* do/do not)
4. **Affective blunting**/(Snap prop): Decreased expression of feelings

TABLE 20.13: Kurt Schneider's 11 first rank symptoms of schizophrenia.

Three thought phenomenon	**Three disorders of perception;** auditory hallucinations
1. Thought insertion 2. Thought withdrawal 3. Thought broadcasting	1. 1st person (Thought Echo) 2. 2nd person (Command Hallucination) 3. 3rd person (Running commentary)
Three made phenomenon	**Two special phenomenon**
1. Made impulse 2. Made volition 3. Made affect	1. Somatic passivity 2. Delusional perception

Schneider's First Rank Symptoms of Schizophrenia

See **Table 20.13.**

Subtypes of Schizophrenia

Major Subtypes of Schizophrenia (Table 20.14)

1. **Paranoid schizophrenia:**
   - Most common type of schizophrenia, has good prognosis
   - Predominant features include: Delusions and hallucinations that are persecutory/grandiose or of reference/control
2. **Disorganized (Hebephrenic) schizophrenia:**
   - Predominant features of disorganization of behavior, speech, affect, volition
   - Marked thought disorder, incoherence, loosening of associations
   - Emotional disturbances—blunted effect, and **senseless giggling**
3. **Catatonic schizophrenia** has marked disturbance of motor behaviors:
   Clinical forms:
   - Excited catatonia: Increase in psychomotor activity (restlessness, agitation, excitement aggressiveness) and increase in speech production
   - Stuporous (retarded) catatonia: Extreme retardation of psychomotor function
   - Catatonia alternating between excitement and stupor: Features of both the above forms
4. **Simple schizophrenia:** Has predominant negative symptoms
5. **Schizophrenia undifferentiated type:** Meets criteria for schizophrenia. Do not meet criteria for other schizophrenia types.

Note: *Subtyping of schizophrenia has been removed in DSM-5/ICD-11 versions*

ICD-11 Course Specifiers for Schizophrenia

- 1st episode: No past episodes
- Multiple episodes: At least 1 past episode with significant remission of symptoms between current and last episode
- Continuous: No remission of symptoms, illness present for >1 year

Typical **stages** of schizophrenia: Prodromal phase, active phase, and residual phase

Investigation of schizophrenia

- Full neurological examination: Gait and motor
- Cognitive examination: MMSE
- Blood: Complete blood count, liver function tests, renal function tests, thyroid functions tests, and glucose
- Urine drug screen
- EEG if suspicion of temporal lobe epilepsy
- Brain imaging findings:
  - CT: Lateral and third ventricular enlargement, reduction in cortical volume
  - MRI: Increased cerebral ventricles
  - PET: Hypoactivity of the frontal lobes

TABLE 20.14: Types of schizophrenia.

Characteristic	*Type I*	*Type II*
Predominant symptoms	Positive	Negative
Onset	Acute	Insidious
Premorbid functioning	Good	Poor
Cognition	Intact	Impaired
Changes in brain	Increased dopamine in mesolimbic pathway	Ventriculomegaly on CT
Reversibility	Reversible	Irreversible
Response to treatment with antipsychotics	Good	Poor
Prognosis	Good	Poor

Management of Schizophrenia/Psychosis

Q. PS5.3 Describe the treatment of schizophrenia including behavioral and pharmacologic therapy.

Q. PS5.5 Enumerate and describe the pharmacologic basis and side effects of drugs used in schizophrenia.

Management of schizophrenia

Hospital admission is necessary for a first episode to permit a full physical and psychiatric assessment.

Indications for hospital admission

Indications include suicidal tendencies, violent behavior, severe psychosis, catatonic schizophrenia, noncompliance and failure of outpatient treatment.

Drug treatment [Antipsychotics (atypicals preferred) + Benzodiazepines] are the mainstay of treatment in acute phase.

Psychological treatment

It is an essential component of management in maintenance phase of treatment.

- Psychoeducation can prevent relapse by enhancing insight.

- Cognitive remediation to challenge delusions.
- Social skill training: Improve relationship.
- Behavioral: Positive reinforcement of desirable behavior.
- Family therapy: To reduce expressed emotion (EE). (High EE include hostility, over involvement, critical comments from family; hence reduce relapse rate).

Social treatment

- After the control of an acute episode of schizophrenia, social rehabilitation may be needed.
- Patients with chronic schizophrenia may need long-term, supervised accommodation.

Other treatments

- Rehabilitation to enhance self-care, compliance and insight.
- ECT (electroconvulsive therapy) is for catatonic schizophrenia.

Prognosis

- **Rules of quarters:** Complete remission (25%), good recovery (25%), partial recovery (25%) and downhill course (25%).
- **Good prognostic factors:** Late onset, female gender, married, and presence of precipitating event.

OTHER PSYCHOTIC DISORDERS

Based on **duration of symptoms schizophrenia-like disorders** can be further differentiated as:

- **<1 month:** Acute and transient psychotic disorder/brief psychotic disorder
- **1–6 months:** Schizophreniform disorder
- **>6 months:** Schizophrenia

Schizophreniform Disorder (> Month but <6 Months)

- **Presenting symptoms:** Same as in schizophrenia (hallucinations, delusions, disorganized speech, grossly disorganized or catatonic behavior, negative symptoms, social and/or occupational dysfunction).
- **Difference from schizophrenia:** Symptoms are present >1 month but <6 months and most of the patients return to their baseline level of functioning.

Treatment

- Must assess whether the patient needs hospitalization, to assure safety of patient and/or others.
- Antipsychotic medication is indicated for a 3–6-month course.
- Individual psychotherapy.

Schizoaffective Disorder

- **Presenting symptoms:** Mood disorders (major depressive episode, manic episode, or mixed episode) + psychosis (schizophrenia).
- Delusions or hallucinations for at least 2 weeks in the absence of mood symptoms.
- **Prognosis:** Better prognosis than patients with schizophrenia. Worse prognosis than patients with affective (mood) disorders.
- **Treatment:** Antipsychotics, mood stabilizers ± antidepressants medications

MOOD DISORDERS

- Mood or affective disorders are among the most common diagnoses in psychiatry.
- Mood refers to a pervasive and sustained emotional state (as differentiated from affect, which is immediately expressed and observed emotion).
- Mood disorders are characterized by a disturbance of mood and behavior.
- It can either be unipolar (depression/mania) or bipolar.

Q. PS6.1 Classify and describe the magnitude and etiology of depression.

Categories/Classification of Mood Disorder (Table 20.15 and Fig. 20.3)

- **Unipolar depression:** Only one end of the emotion spectrum and characterized by one or more episodes of low mood and associated symptoms (depression form).

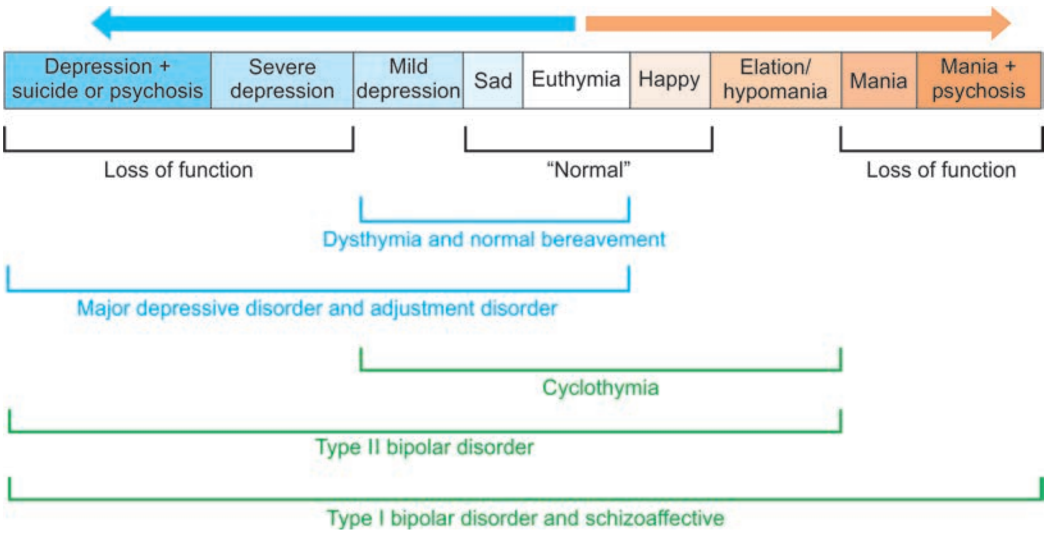
- **Dysthymic disorder:** Characterized by chronic low-grade depressed mood without sufficient other symptoms to count as "clinically significant" or "major" depression.
- **Bipolar disorder:** Cycling between both ends of the emotion spectrum and characterized by episodes of elevated mood interspersed with episodes of depression (both manic and depression).

Mood (affective) disorders can be classified into **primary and secondary**.

- In **primary** affective disorder, the affective episodes (mania or depression) are **not secondary to any other psychiatric** or physical illness.
- In **secondary** affective disorder, the affective episodes **are secondary to another psychiatric or physical illness.**

TABLE 20.15: Classification of mood disorder.

Unipolar	*Bipolar*	*Mood disorders with known etiology*
Major depressive disorder	Bipolar I disorder	Substance-induced mood disorder
Dysthymic disorder	Bipolar II disorder	Mood disorder due to general medical condition
	Cyclothymic disorder	Depression, mania, bipolar disorders, depression—affect, mood, and syndrome



Depression + suicide or psychosis
Severe depression
Mild depression
Sad
Euthymia
Happy
Elation/ hypomania
Mania
Mania + psychosis
Loss of function
"Normal"
Loss of function
Dysthymia and normal bereavement
Major depressive disorder and adjustment disorder
Cyclothymia
Type II bipolar disorder
Type I bipolar disorder and schizoaffective

FIG. 20.3: Spectrum of mood disorder.

Unipolar Depression/Major Depressive Disorder

Q. Describe the etiology, clinical features and management of depression.

Depressive disorders are characterized by persistent low mood, loss of interest, and reduced energy that usually impairs day-to-day functioning.

- It is more common in middle-aged females.
- **Number of episodes:**
  - ***Single episode*** of major depression.
  - ***Recurrent*:** Two or more episodes of major depression.
  - ***Persistent depressive disorder*** (dysthymia): Low mood persisting for more than 2 years
- Risk of suicide in an individual with a depressive disorder is 10 times more than that in the general population.

Etiology

- ***Trimonoaminergic depletion:*** Reduced levels of serotonin, epinephrine, and dopamine are seen in depression
- ***HPA axis dysfunction:*** Evident through blunted response to dexamethasone suppression test
- ***Hypothyroidism***
- ***Pathology of left side of the brain:*** Predominantly involving prefrontal cortex, amygdala, hippocampus, and anterior cingulate cortex
- ***Aaron T Beck's cognitive triad of depression:*** Negative thoughts about self (worthlessness), environment (helplessness), and future (hopelessness)

Q. PS6.2 Enumerate, elicit, describe and document clinical features in patients with depression.

Major depressive disorder is characterized by one or more major episodes of depression **(Box 20.1)**.

Reactive depression is a type of clinical depression that is precipitated by events in the individuals life (to be differentiated from normal grief) arising as a consequence of severe traumatic events in life (e.g., the loss of home in a fire). Reactive depression becomes a clinical concern if the depression lasts too long without signs of recovery or if the depression becomes too deep (e.g., leading to suicidal feelings). Most of the time, reactive depression resolves itself.

Melancholic/endogenous depression:

- Depression that occurs in the absence of external life stressors
- Mostly seen in elderly
- Characterized by severe anhedonia, severe vegetative symptoms (early morning awakening, decreased appetite), profound guilt, and suicidal thoughts.

Box 20.1: Diagnostic criteria for major depressive episode.

General criteria for a major depressive episode require five or more of the below symptoms to be present for at least 2 weeks; one symptom must be ***depressed mood or loss of interest or pleasure.*** *The symptoms must also cause* ***distress or impairment****.*

- **Mood:** Depressed mood most of the day, nearly every day (dysphoria)
- **Interest:** Marked decrease in interest and pleasure in most activities (anhedonia)
- **Energy:** Fatigue or low energy nearly everyday
- **Concentration:** Decreased concentration or increased indecisiveness
- **Sleep:** Insomnia or hypersomnia
- **Appetite:** Increased or decreased appetite or weight gain or loss
- **Psychomotor:** Psychomotor agitation or retardation
- **Guilt:** Feelings of worthlessness or inappropriate guilt
- **Suicidality:** Recurrent thoughts of death, suicidal ideation, suicidal plan, and suicide attempt

Q. PS6.4 Describe the treatment of depression including behavioral and pharmacologic therapy.

Treatment of depression

Both drug and psychotherapy (e.g., cognitive behavioral therapy, interpersonal therapy) are effective in the treatment of depression either alone or in combination. Medication alone also can relieve symptoms. However, the combined approach generally provides the patient with the quickest and most sustained response.

Drug treatment (pharmacotherapy)

All antidepressants are potentially effective in patients whose depression is secondary to medical illness, as well as those in whom it is the primary problem. They are effective in moderate and severe depression. Usually, 2–6 weeks at a therapeutic dose level are needed to observe a clinical response. Commonly used antidepressants are listed in **Table 20.5**.

Psychological treatments

- Mild-to-moderate depression: Both cognitive behavioral therapy (CBT) and interpersonal therapy (IPT) are as effective.
- Severe depression: Antidepressant drugs are preferred.

Nonpharmacologic treatments

- Electroconvulsive therapy (ECT): Highly effective for depression and may have a more rapid onset of action than drug treatments. ECT may be indicated if patient is suicidal or worried about side effects from medications.
- Other magnetic and electrical stimulatory methods like r-TMS

Acute Mania (Tables 20.16 to 20.18)

Q. Describe the etiology, clinical features and management of mania.

Mania is an abnormally elevated mood state.

TABLE 20.16: Clinical features of acute mania.

Changes in mood Cheerfulness, irritability, excitability, exhilaration, hostility, anxious	**Changes in speech** Rapid, pressured speech, talkativeness, clang associations	**Changes in thinking** Distractibility, flight of ideas, creative/disjointed/racing/expansive thoughts	**Changes in perceptions** Inflated self-esteem, feeling superior, hallucinations, paranoia
Increased energy and activity Little fatigue despite decreased need for sleep, increased productivity, doing several things at once, making lots of plans, taking on too many responsibilities, restlessness, difficulty staying still		**Impaired judgment** Lack of insight, inappropriate humor and behaviors, impulsive or thrill-seeking behaviors: increased alcohol consumption; financial extravagance; dangerous driving; sexual promiscuity	**Increased social behavior** Unnecessary phone calls, increased sexual activity, talkative and sociable, indiscretions in eating habits

TABLE 20.17: Diagnostic criteria for manic episode.

Three to four of the following criteria are required during the elevated mood period.

1. Self-esteem: Highly inflated, grandiosity	5. Attention: Easy distractibility
2. Sleep: Decreased need for sleep, rested after only a few hours	6. Activity: Increased goal-directed activity
3. Speech: Pressured	7. Hedonism: High excess involvement in pleasurable activities (sex, spending, travel)
4. Thoughts: Racing thoughts and flight of ideas	

TABLE 20.18: Elevated mood: It has four stages depending on severity of manic episodes.

Stage	*Features*
1. Euphoria (Stage I) Hypomania	Increased sense of psychological well-being and happiness not in keeping with ongoing events
2. Elation (Stage II)	Moderate elevation of mood with increased psychomotor activity
3. Exaltation (Stage III)	Intense elation of mood with delusions of Grandeur
4. Ecstasy (Stage IV)	Severe elevation of mood, intense sense of rapture, or blissfulness seen in delirious or stuporous mania

Treatment of Mania

- Hospitalization: To avoid injury to self/others, to control agitation and to ensure medication compliance
- Mood stabilizing agents (discussed earlier)
- Antipsychotics
- Electroconvulsive therapy (ECT) (discussed earlier)

Bipolar Disorder

Q. PS7.1 Classify and describe the magnitude and etiology of bipolar disorders.

Q. PS7.2 Enumerate, elicit, describe and document clinical features in patients with bipolar disorders.

Q. PS7.4 Describe the treatment of bipolar disorders including behavioral and pharmacologic therapy.

Bipolar disorder is characterized by episodes of elevated mood (mania/hypomania) interspersed with episodes of depression.

- Elevated mood when mild or short-lived (4 days) is known as hypomania, or when severe or chronic (at least 1 week), is called mania.
- The lifetime risk of developing bipolar disorder is about 1–2%. The lifetime risk of suicide is about 5–10%.
- **Types:** As per DSM-5, bipolar disorders are divided into: bipolar I disorder, bipolar II disorder, cyclothymic disorder, substance/medication-induced bipolar disorder, and bipolar disorder due to another medical condition.
    - **Bipolar I disorder:** It is characterized by the occurrence of one or more manic or mixed episodes (usually), and usually one or more major *depressive* episodes.
    - **Bipolar II disorder:** It is characterized by the occurrence of one or more major depressive episodes, at least one *hypomanic* episode and without any manic or mixed episode.

Management of Bipolar Disorders

- Mood stabilizing agents (discussed earlier) + Antipsychotics/Antidepressants (based on features of presenting episode)
- Electroconvulsive therapy (ECT) (discussed earlier)

Cyclothymic Disorder

It is characterized by:

- Chronically fluctuating mood states; periods of hypomania and depression
- Duration of at least 2 years in adults and 1 year in adolescents and children
- Individual is not without symptoms for more than 2 months at a time.
- There are no major depressive, manic, or mixed episodes during the initial 2 years. After the initial 2 years, there may be superimposed manic, mixed, or depressive episodes.

OBSESSIVE-COMPULSIVE DISORDER

Q. Describe the etiology, clinical features and management of OCD.

Obsessive-compulsive disorder (OCD) is characterized by obsessive, recurrent, unwanted thoughts (which cause marked anxiety) and by compulsions (which serve to neutralize or relieve anxiety).

- **Obsessions:** These are persistent *thoughts, ideas, impulses, or images* that seem to invade a person's consciousness.
- **Compulsions:** Repetitive behaviors (e.g. handwashing, ordering, checking) or mental acts (e.g., praying, counting, repeating words silently) that the individual feels driven to perform in response to an obsession.

Etiology

Cortico-striatal-thalamo-cortical circuit dysfunction.

Types

People have symptoms like:

- Cleaning: Fears of contamination
- Symmetry: Arranging items symmetrically and repeating, ordering, and counting compulsions
- Forbidden or taboo thoughts: Aggressive, sexual, and religious obsessions.
- Harm (e.g., thoughts about harm on oneself or others).

Management

Antidepressant drugs (SSRIs-fluoxetine, fluvoxamine and TCA-clomipramine) and to psychotherapy (behavioral, supportive). However, relapses are common and it often becomes chronic. Antipsychotics like Risperidone may be tried as adjuvants. ECT/Cingulotomy/capsulotomy can be used in refractory cases.

Other OCD-related Disorders

- Trichotillomania
- Skin picking/excoriation disorder
- Hoarding disorder: Difficulty in disposing items regardless of its value
- Body dysmorphic disorder

IMPULSE CONTROL DISORDERS

- Impulsive disorder is defined as a sudden and irresistible force which compels a person to do some action without motive or forethought. A normal person always tries to analyze his actions whether they are consistent with law or not. Once he realizes that his action may be contrary to law he stops it.
- But in impulsive disorder, a person is not able to control himself. Examples:
    - Kleptomania: An irresistible desire to steal things usually of low value.
    - Pyromania: An irresistible desire to set things on fire.
    - Megalomania: An irresistible impulse to maim animals.
    - Dipsomania: An irresistible impulse to drink at periodic intervals.
    - Sexual impulses: All sexual perversions.
    - Homicidal impulses: To kill some persons.
    - Suicidal impulses: To commit suicide. Impulses are quite commonly seen in various mental disorders like depression, schizophrenia, mania, etc.
    - Trichotillomania: It is an irresistible desire to pull out one's own hair.
    - Oniomania: Compulsive desire to shop (shopping addiction).

NEUROTIC DISORDERS

Neurotic disorders can be:

- Anxiety symptom predominant disorders
- Disorders occurring after stress/trauma
- Somatic symptom predominant disorders
- Dissociative disorders

Anxiety Symptom Predominant Disorders

	Generalized anxiety disorder	***Panic disorder***	***Phobia***
Anxiety symptoms	Continuous	Episodic, unprovoked	Episodic; on exposure to phobic stimulus

ANXIETY DISORDERS

Q. Describe the etiology, clinical features and management of anxiety disorders.

Q. PS8.1 Enumerate and describe the magnitude and etiology of anxiety disorders.

- Anxiety disorders are characterized by unrealistic, irrational fear or anxiety of disabling intensity, worrisome thoughts, avoidance behavior, and the somatic symptoms of autonomic arousal.
- Anxiety is a syndrome with psychological (insecurity, worry, apprehension) and physiologic (sympathetic activation) components. Patients with anxiety may also have depression.

Types of Anxiety Disorder

See **Table 20.19.**

TABLE 20.19: Differences between anxiety disorders.

Characteristics	*Generalized anxiety disorder*	*Panic disorder*	*Phobic anxiety disorder*
Occurrence	Persistent	Paroxysmal	Situational
Symptoms	Persistent	Episodic	On exposure
Cognitions	Worry	Fear of symptoms	Fear of situation
Behavior	Agitation	Escape	Avoidance

Q. PS8.2 **Enumerate, elicit, describe and document clinical features in patients with anxiety disorders.**

Generalized Anxiety Disorder (GAD)

- It is a chronic state associated with uncontrollable excessive and free floating anxiety and worry persisting for minimum 6 months.
- **Symptoms:** It is associated with somatic symptoms of muscle tension and bowel disturbance, sleep disturbance, and difficulty concentrating or mind going blank.

Panic (Paroxysmal) Disorder

- Panic disorder is defined as the occurrence of recurrent unexpected attacks of intense anxiety that include marked physical symptoms, such as tachycardia, chest pain, hyperventilation, dizziness, trembling, numbness, and sweating.
- Panic disorder may occur with or without agoraphobia (avoidance of situations where a person may feel trapped and unable to escape). A discrete period of intense fear or discomfort which develops abruptly and reaches a peak within 10 minutes. In between the attacks, patient is free from anxiety.
- Age of onset for panic disorder varies but lies between late adolescence and mid-30s.
- Patients have persistent concern of having attack and they worry about the implications of attack.

Phobic Anxiety Disorder

A phobia is an *abnormal or excessive, persistent and disproportionate fear of an object or situation* that presents little or no actual danger to the person. It causes avoidance of it (e.g., excessive fear of dying in an air crash leading to avoidance of flying). Phobic responses can develop to general medical procedures, such as venipuncture.

Types of Phobia

- **Specific phobia:** Fear of specific situation/object. It is characterized by clinically significant anxiety provoked by exposure of specific feared object or situation, often leading to avoidance.
- **Social phobia:** Fear of socially demanding situations. It is characterized by clinically significant anxiety provoked by exposure to certain types of social or performance situation, which people are exposed to unfamiliar people or to scrutiny by others.
- **Agoraphobia:** Fear of places from where escape is difficult. It is generalized phobia (marked fear) of going out alone or being in crowded places. Thus, avoid being alone or being in a public place (e.g., bridges, tunnels, crowds, etc.).

List of phobias:
- **Claustrophobia:** Fear of being in constricted, confined spaces
- **Aerophobia:** Fear of flying
- **Arachnophobia:** Fear of spiders
- **Zoophobia:** Fear of animals
- **Aquaphobia:** Fear of water
- **Acrophobia:** Fear of heights

Differential diagnosis of anxiety disorders.

Physical illness which mimic anxiety disorder: Hyperthyroidism, pheochromocytoma, hypoglycemia, paroxysmal atrial arrhythmias, alcohol withdrawal, and temporal lobe epilepsy.

Q. PS8.4 **Describe the treatment of anxiety disorders including behavioral and pharmacologic therapy.**

Management of Anxiety Disorders

Psychological management:
- Explanation and reassurance
- Relaxation training, graded exposure (desensitization) to feared situations for phobic disorders, flooding and implosive therapy and cognitive behavioral therapy (CBT).

Pharmacological management:

Drugs of choice are antidepressants (SSRI). Benzodiazepines are useful in the short-term but long-term use can result in dependence. When somatic symptoms are prominent, β-blocker (e.g., propranolol) may be used.

Q. PS9.1, 9.2 and 9.4 Describe the etiology, clinical features and management of stress related disorders.

Disorders Occurring After Stress/Trauma

Following sudden, life-threatening trauma/stress		After gradual routine life stress
Symptom duration <1 month	Symptom duration >1 month	**Adjustment disorder**
Acute stress reaction	**Post-traumatic stress disorder**	

Post-traumatic Stress Disorder

- It is characterized by the re-experiencing (recurrent bouts) of an extremely traumatic event accompanied by the symptoms of increased arousal and by avoidance of stimuli associated with trauma.
- The traumatic event (e.g., a military experience, a physical or sexual assault, a motor vehicle accident, a natural disaster) involved may have caused death or near death experience or serious injury to self or others.
- Typically, patients re-experience the traumatic event (e.g., nightmares, flashbacks intrusive recollections), engage in avoidance of trauma or talk of trauma, or recollections of stimuli associated with the sentinel trauma. Patients experience increased autonomic reactivity, such as hypervigilance, irritability, insomnia startle responses, etc.

Classification of PTSD

- ***Acute PTSD:*** Symptoms begin within 3 months of trauma or the duration of symptoms is <3 months.
- ***Chronic (or delayed) PTSD:*** Symptoms start >3 months after trauma (delayed) or persist for 3 months or longer.
- ***With delayed onset:*** 6 months have passed between the traumatic event and the onset of symptoms.

Management: Psychological (Eye movement desensitization psychotherapy) and pharmacological (antidepressants and benzodiazepines)

Q. PS10.1, 10.2 and 10.4 Describe the etiology, clinical features and management of Somatoform disorders.

SOMATOFORM DISORDERS

These disorders have somatic symptoms which are not explained by a medical condition (medically unexplained symptoms), nor better diagnosed as part of a depressive or anxiety disorder.

Somatic Symptom Predominant Disorders

- Preoccupation with symptoms: **Somatization**/somatic symptom disorder
- Preoccupation with pain: **Somatoform pain** disorder
- Preoccupation with diagnosis: **Hypochondriasis**/illness anxiety disorder
- Preoccupation with imagined defect: **Body dysmorphic disorder**

DISSOCIATIVE (CONVERSION) DISORDER

Q. PS10.1, 10.2 and 10.4 Describe clinical features and management of dissociative (conversion) disorders.

- It was formerly called **hysteria** and this old term was replaced in DSM-IV and ICD-10 by new term dissociative disorder. It is called functional neurological symptom disorder in DSM-5.
- Etiology: Unresolved psychological conflict is converted acutely and unconsciously into sensorimotor neurological symptoms → maladaptive coping mechanism.
- More common in women and children.
- Definition: Dissociative disorder is a syndrome characterized by a loss or distortion of neurological function which cannot be fully explained by organic disease.
- Psychological functions commonly affected include conscious awareness and memory. Physical functions affected (conversion) include changes in sensory or motor function. These changes may resemble lesions in the motor or sensory nervous system.

Etiology

- Unconscious psychological process: Patient lacks insight into nature of symptoms. It is maladaptive way of coping with an unresolved psychological conflict by becoming ill.
- An association of this disorder with adverse childhood experiences, including physical and sexual abuse, is being observed.

Clinical Features

- Primary gain: Keeps internal conflicts outside patient's awareness.
- Secondary gain: Benefits received from being "sick".
- *La belle indifference:* Patient seems unconcerned about impairment.
- Gait disturbance
- Loss of function in limbs
- Aphonia
- Pseudoseizures (nonepileptic seizures)
- Sensory loss
- Blindness

Types of Dissociative Disorders

- Dissociative **amnesia:** Patchy loss of autobiographical memory
- Dissociative **fugue:** Amnesia + travel, attains new identity
- Dissociative **identity disorder:** ≥2 identities in a person at a time
- **De-personalization** and **derealization** disorder: "As if" change in person/environment respectively.

Management of Dissociative Disorder

- Physical and psychiatric examination to exclude organic disease.
- Explanation and reassurance.
- Psychodynamic therapy—resolution of psychological conflict.
- Resistant cases: Abreaction under hypnosis or small IV dose of pentanol.

Based on Symptom Production

Symptom production	***Unconscious***	***Conscious***	
		With motive to obtain benefit	***Without motive***
Example	**Somatoform disorder** **Dissociative disorder**	**Malingering**	**Factitious disorder/Munchausen syndrome**

Malingering

It is an uncommon disorder characterized by the repeated and deliberate production of the signs or symptoms of disease to gain medical care (e.g., dipping of thermometers into hot drinks to fake a fever).

FACTITIOUS DISORDER/MUNCHAUSEN'S SYNDROME

- It is a rare, severe, chronic form of factitious disorder named after the *German Baron von Munchausen*, who was legendary for his inventive lying.
- He traveled widely, sometimes visiting several hospitals in one day. Patient frequently changes his name, with history of doctor shopping.
- These patients are memorable because they present so dramatically. They usually seek medical attention at night when junior doctors or residents are on duty. They fabricate a convincing history and present to the doctor with dramatic symptoms of a medical emergency. They persuade an inexperienced doctor to undertake investigations or initiate treatment including exploratory surgery.
- Abdomen may show several scar marks ("surgical battlefield") due to previous operations.

Management

- Gentle and firm confrontation with clear evidence of the fabrication of illness.
- Psychological support.
- Recognition of the condition to avoid further iatrogenic harm.

Q. PS12.1, 12.2 and 12.4 Describe clinical features and management of psychosomatic disorders.

PSYCHOSOMATIC DISORDER

Psychosomatic disorder is characterized by presence of organic pathology, but is altered by psychological influence. It includes those disorders which are either initiated or exacerbated by the presence of meaningful psychosocial environmental stressors.

Treatment of Psychosomatic Disorders

Cognitive behavior therapy (CBT) is often the treatment of choice for a psychosomatic disorder. This therapy helps patients learn new ways to cope with and solve their problems as they gain a deeper understanding of their condition or circumstances. Patients will also learn to set realistic life goals and identify and change behaviors or thoughts that have negative effects on their lives.

Classical psychosomatic illnesses:
- Bronchial asthma
- Ulcerative colitis
- Peptic ulcer
- Neurodermatitis
- Thyrotoxicosis
- Rheumatic arthritis
- Essential hypertension

ORGANIC MENTAL DISORDERS (TABLE 20.20)

Q. Enumerate and describe common organic psychiatric disorders: etiology, clinical features and management.

TABLE 20.20: Organic mental disorders.

Characteristic	***Delirium***	***Dementia***	***Amnestic disorder***
Onset	Acute	Chronic	Chronic
Course	Fluctuating	Progressive	Progressive
Sensorium	Altered	Clear	Clear
Cognitive functions affected	Multiple: ➢ Poor attention and concentration: Recent memory affected ➢ Remote memory normal	Multiple: ➢ Amnesia (Remote + recent) ➢ Apraxia ➢ Agnosia ➢ Aphasia ➢ Loss of executive functions	Only memory affected Recent > remote
Confabulations (filling up gaps in memory)	Absent	Absent	Present
Psychotic symptoms	➢ Present ➢ Fleeting paranoid delusions ➢ Transient visual hallucinations	➢ Present ➢ Fixed paranoid delusions ➢ Auditory, visual hallucinations	Absent
Cause	Metabolic, infective, endocrine, drug intoxication/withdrawal	➢ Reversible: Depression, NPH, B_{12} deficiency, hypothyroidism ➢ Irreversible: Alzheimer's, vascular, Lewy body, frontotemporal	B_{12} deficiency: Korsakoff's amnestic syndrome
Management	Treat the underlying cause	Antidementia drugs	B_{12} supplementations

DELIRIUM

Definition

It is an acute organic mental disorder characterized by confusion, restlessness, incoherence, inattention, anxiety, or hallucinations which may be reversible with treatment.

Clinical Features

- **Acute course:** Sudden onset, short episode.
- Global impairment of cognitive functions (memory, attention, orientation, thinking, etc.).
- Fluctuating course.
- **Cardinal features:**
  - Clouding of consciousness, impaired alertness, awareness, and attention.
  - Variability in state of arousal.
  - Reduced responsiveness is interspersed with periods of excited outbursts.
  - Sleep/wake cycle disrupted.
- Impaired perception: Misperceives surrounding and attendants, hallucinations.
- Disturbance of emotion: Agitation, fear, depression, and anxiety.
- Psychomotor changes: Hyperactivity, restlessness, and repetitive (plucking, tossing).

Predisposing and precipitating factors of delirium are shown in **Table 20.21** and causes of delirium are shown in **Table 20.22**.

TABLE 20.21: Predisposing and precipitating factors of delirium.

Predisposing	***Precipitating***
➢ Diseases of brain: Dementia, stroke, and past severe head injury ➢ Drugs: Sedatives and anticholinergics ➢ Impairments of special senses: Sight and hearing ➢ Multiple severe illnesses ➢ Malnutrition	➢ **Iatrogenic:** Unpleasant environmental change, invasive procedures, new medications, trauma, dehydration, ongoing malnutrition, and elimination malfunction ➢ **Illnesses:** Infections, intracranial pathologies, impaired organ function, abnormal metabolite function, pain, and drug withdrawal

TABLE 20.22: Causes of delirium.

➢ Metabolic causes: – Hypoxia, CO_2 narcosis – Hypoglycemia – Hepatic encephalopathy – H_2O and electrolyte imbalance	➢ Endocrine causes: – Hypo- and hyperpituitarism – Hypo- and hyperthyroidism – Hypo- and hyperparathyroidism – Hypo- and hyperadrenalism
➢ Drugs and poisons: – Digitalis – Alcohol – Tricycle antidepressants – Salicylates, penicillin, etc.	➢ Intracranial causes: – Epilepsy – Head injury – Meningitis – Migraine
➢ Nutritional deficiencies: – Thiamin, niacin – Proteins	➢ Miscellaneous: – Postoperative states – Sleep deprivation – Acute and chronic systemic infections – Febrile delirium in children

Investigations

If cause is not obvious: Complete blood count, urine analysis, blood glucose, blood urea, serum electrolytes, liver and renal function tests, arterial blood gases, thyroid function test, X-ray chest, ECG, CSF, VDRL, HIV-testing, EEG, and cranial CT scan or MRI scan.

Management: Identify the cause and treat it accordingly
- Chlorpromazine (50–100 mg 8th hourly) or haloperidol (5–10 mg 8th hourly) are the drugs of choices except in delirium tremens, where benzodiazepines (BZDs) or diazepam 10–20 mg 6th hourly is preferred.
- Also give supportive medical and nursing care.

Differences between delirium, dementia, and psychosis are shown in Table 20.23.

TABLE 20.23: Differences between delirium, dementia and psychosis.

Condition	*Onset*	*Pattern*	*Orientation*	*Attention*	*Memory*	*Duration*
Delirium	Acute	Fluctuating	Usually impaired	Impaired/fluctuating	Impaired	Hours or days
Dementia	Insidious	Progressive	Normal or impaired	~Normal	Impaired	Months or years
Psychosis	Variable	Variable	~Normal	Normal or impaired	Normal or impaired	Variable

SUBSTANCE USE DISORDERS

Q. Write short notes on substance use, its effects, and treatment.

- **Substance use includes harmful use, dependence, effects of intoxication and withdrawal**
- ***Harmful use:*** Substance use pattern that causes harm to individual's physical/mental health or has caused harm to others through the behavioral changes.
- ***Dependence:*** Due to continuous use of substance, individual has become dependent on the substance and unable to regulate the pattern of his use. Manifestation can either psychological or physiological.
- Psychological manifestations can be seen as craving (strong desire to use the substance), loss of control in using substance, continuing use despite harmful consequences, and prioritizing substance use while neglecting alternate activities for pleasure.
- Physiological manifestations can be seen by symptoms of tolerance and withdrawal.
- ***Tolerance:*** It is defined by either of the following:
  - A need for markedly increased amounts of the substance to achieve intoxication or desired effect.
  - A markedly diminished effect with continued use of the same amount of the substance.
- ***Substance intoxication:*** Reversible, substance-specific syndrome caused by the recent ingestion of or exposure to a substance.
- ***Substance withdrawal:*** Characteristic substance-specific, maladaptive behavioral change, with physiologic and cognitive concomitants, caused by the cessation of or reduction in heavy and prolonged substance use.

TABLE 20.24: Common symptoms and signs of substance abuse.

Symptoms	*Signs*
➢ Frequent absences from school or workplace	➢ Tremors
➢ Depression/anxiety	➢ Tachycardia
➢ Epigastric distress, diarrhea	➢ Labile hypertension
➢ Sleep disorders	➢ Conjunctival injection
➢ Sexual dysfunction	➢ Odor of alcohol on breath in alcohol use
➢ Frequent trauma/injury	➢ Tender hepatomegaly

Risk Factors/Etiology (Table 20.24)

- **Family history:** Parental drug use, marital conflict, and disturbed family environment.
- **Physiology:** Individuals who are innately more tolerant to substance.

- **Developmental history:** Poor parenting, childhood physical and sexual abuse.
- **Environmental:** Peer pressure, economic disadvantage, and social isolation. Availability and access to drugs.
- **Psychiatric illness:** Conduct disorder, depression, and bipolar disorder.
- **Age group:** Highest prevalence of substance abuse is between 18 and 22 years of age. Experimentation with gateway drugs may start as early as preadolescence.

Investigations and Diagnosis

Diagnosis may be apparent from the history or may be made when the patient presents with a complication.

Laboratory Toxicology

- **Breath, blood, and urine examination:** Screen for types of substances of abuse and its concentrations.
- **Intravenous drug abuse workup:**
  - HIV, hepatitis B, hepatitis C, and tuberculosis.
  - Drug screening of samples of urine or blood will help in confirming the diagnosis.
- Other laboratory studies for evidence of systemic damage from substance use.

Treatment of Substance-related Disorders

Biological treatment: Pharmacologic intervention to ameliorate psychological or physical symptoms.

- **Agonist substitution:** Safe drug with a similar chemical composition as the abused drug (e.g., methadone for heroin addiction).
- **Antagonistic treatment:** Drugs that block Treatment of Substance-related Disorders ck or counteract the positive effects of substances (e.g., naltrexone for opiate and alcohol problems).
- **Aversive treatment:** Drugs that make the injection of abused substances extremely unpleasant (e.g., disulfiram for alcoholism and silver nitrate for nicotine addiction).

Psychosocial treatment

- Community support programs: These are strongly encouraged.
- Emotional reassurance and providing a structured and secure environment.
- Components of comprehensive treatment and prevention programs: Individual and group therapy, aversion therapy and convert sensitization, contingency management, community reinforcement, relapse prevention, and preventative efforts via education.

Main Categories of Substances

- **Depressants:** Result in behavioral sedation (e.g., alcohol, sedatives, anxiolytic, and hypnotic drugs).
- **Stimulants:** Increase alertness and elevate mood (e.g., cocaine, nicotine, caffeine, and amphetamines).
- **Opiates:** Primarily produce analgesia and euphoria (e.g., heroin, morphine, codeine, and brown sugar).
- **Hallucinogens:** Alter sensory perception [e.g., marijuana (cannabis), lysergic acid diethylamide, phencyclidine]
- **Club/rave party drugs**: Cause anterograde amnesia (e.g., gamma hexane butyrate, flunitrazepam, and ketamine)
- **Other drugs of abuse:** Includes volatile solvents, anabolic steroids, and medications.

NICOTINE

Nicotine withdrawal: Symptoms in chronic users appear about 30 minutes after every dose. These include confusion, anxiety, restlessness, insomnia, depression, frustration and anger, nightmares, and headache.

Treatment of Tobacco Use Disorder

- **Smoking cessation**
- Cognitive behavioral therapy (CBT)
- Nicotine gum or lozenge, transdermal patch, and nasal spray inhalers
- Medication:
  - **Bupropion:** It is an antidepressant which is chemically unrelated to tricyclic antidepressants or SSRIs. Dose 150 mg po twice a day.
  - **Varenicline and cytisine:** It is an alpha-4 beta-2 nicotinic receptor partial agonist more effective than nicotine and bupropion. Dose 1 mg po bid.

Q. PS4.1, 4.2 and 4.4 **Describe etiology, clinical features and management of alcohol use disorders.**

ALCOHOL

Consumption of alcohol when associated with social, psychological, and physical problems constitutes alcohol use disorder.

Etiology

Alcohol is a central nervous system depressant. It influences several neurotransmitter systems, mainly GABA (inhibition of behavior) but also glutamate system and serotonin system.

Alcohol Dependence

It is characterized by a problematic pattern of alcohol use leading to clinically significant impairment or distress, as manifested by multiple psychosocial, behavioral, or physiologic features.

Features of alcohol dependence

- Loss of control: Engaging in risky behaviors while under the influence.
- Compulsive preoccupation: Worrying compulsively about getting a "fix" and spending a lot of their time thinking about the drug.
- Continued use of alcohol despite negative consequences: Losing control of the ability to monitor how much and how often the user takes their drug.
- Loss of motivation: Losing interest in activities that the user enjoyed prior to addiction.
- Desire to stop drinking, but inability to do so.
- Excessive time spent getting or using alcohol, or recovering from its effects.
- Craving, or preoccupation with drinking.
- Problems stemming from alcohol use; ignoring those problems; drinking despite obvious hazards, including physical danger.
- Retreating from important work, family, or social activities and roles.
- Tolerance: The need to drink more and more alcohol to feel the same effects, or the ability to drink more than other people without getting drunk.
- Withdrawal symptoms: After stopping or cutting back on drinking, symptoms are anxiety, sweating, trembling, trouble sleeping, nausea or vomiting, and, in severe cases, physical seizures and hallucinations. The person may drink to relieve or avoid such symptoms.

Consequences of alcohol harmful use/dependence

Neuropsychiatric

- Depression, suicide
- Alcohol relieves anxiety in the short term, dependence can develop in long-term use
- Alcoholic hallucinosis: auditory hallucinations
- Alcoholic "blackouts": Amnesia for events that occurred during bouts of intoxication in very heavy alcoholic drinkers.
- **Alcohol withdrawal** (discussed below): Maximum symptoms usually develop 2–3 days after the last drink and can produce seizures ("rum fits").
- **Delirium tremens:** It is a form of delirium found with severe alcohol withdrawal.
- Neurological: Peripheral neuropathy, dementia, cerebral hemorrhage, cerebellar degeneration, Marchiafava-Bignami syndrome, subacute combined degeneration of the cord myopathy, ventricular enlargement, and cognitive impairment.
- Wernicke's encephalopathy: Global confusion, nystagmus, ophthalmoplegia, and ataxia
- Korsakoff's syndrome: Short-term memory deficits, confabulation
- **Alcoholic dementia:** It is a global cognitive impairment which may resemble Alzheimer's disease. It does not progress and may improve if the patient abstains from alcohol.
- **Indirect effects on brain:** It may be due to head injury subdural hematoma, hypoglycemia, and encephalopathy.

Medical

- Hepatic: Fatty change and cirrhosis, hepatocellular carcinoma
- Gastrointestinal: Esophagitis, esophageal varices, Mallory-Weiss syndrome, esophageal carcinoma, gastritis, malabsorption, pancreatitis, and parotid enlargement
- Skin: Palmar erythema, spider naevi, Dupuytren's contractures, and telangiectasias
- Cardiac: Cardiomyopathy and hypertension

- Respiratory: Pneumonia and tuberculosis
- Musculoskeletal: Myopathy and fractures
- Endocrine and metabolic: Pseudo-Cushing's syndrome, hypoglycemia, and gout
- Reproductive: Hypogonadism, infertility, and fetal alcohol syndrome

Social: Absenteeism from work, unemployment, marital discord, child abuse, financial difficulties, violence, and traffic offences.

Investigations and Diagnosis

Laboratory detection of alcohol abuse:

- **Breath, blood, and urine examination:** Screen for alcohol.
- **Gamma-glutamyl transpeptidase (GGT):** It is most sensitive for alcohol abuse and is raised in patients with alcohol abuse.
- **Mean corpuscular volume (MCV):** Raised, but is less sensitive than GGT.
- **Carbohydrate-deficient transferrin level:** Elevated and is highly specific in the absence of liver disease.
- **Phosphatidylethanol (PEth)—**concentration >20 ng/dL is evidence of intoxication; it can detect excessive alcohol intake within a 2-week period.
- **Others:** Alanine aminotransferase (ALT), aspartate aminotransferase (AST), and lactate dehydrogenase (LDH).

CAGE questionnaire: Affirmative answers to any two of the following questions (or to the last question alone) are suggestive of alcohol abuse.

- Have you ever felt that you should **Cut** down your drinking?
- Have you ever felt **Annoyed** by others criticizing your drinking?
- Have you ever felt **Guilty** about your drinking?
- Have you ever had a morning drink (**Eye**-opener) after hangover?

Treatment

It involves management of intoxication phase, withdrawal phase, and rehabilitation.

Alcohol Intoxication

Features of Acute Alcoholic Intoxication

- Ataxia, slurred speech, emotional incontinence, and aggression
- Hypotension, gastritis, hypoglycemia, collapse, respiratory depression, coma, and death
- Disturbances in emotional and behavioral state
- Medical symptoms: Due to hypoglycemia, aspiration of vomit, respiratory depression
- Complication of other medical problems
- Accidents, injuries developed in fights

Treatment of acute alcoholic intoxication

- Maintain patent airway and prevent aspiration of vomitus. Tracheal intubation and positive pressure respiration may be needed. Do not use analeptics because they may precipitate convulsions.
- Maintain fluid and electrolyte balance.
- Hypoglycemia is corrected by glucose infusion.
- Thiamine 100 mg in 500 mL glucose solution infused intravenously.

Note: Gastric lavage is helpful only when the patient is brought immediately after alcohol ingestion.

Alcohol Withdrawal

Alcohol withdrawal is characterized by sudden exhibition of central nervous system excitation.

Clinical Features

They occur 6–8 hours after the reduction of ethanol intake and may last for 2–7 days.

- **Minor withdrawal symptoms:**
  - Psychological: Restlessness, anxiety, panic attacks, insomnia, and tremors (the shakes)
  - Autonomic: Tachycardia, palpitations, sweating/diaphoresis, hypertension, pupil dilatation, nausea, vomiting, and hyper-reflexia
  - Others: Gastrointestinal upset, anorexia, and headache
  - They resolve within 24–28 hours.
- **Alcoholic hallucinosis:**
  - These are hallucinations appear within 8–12 hours of abstinence and disappear within 48–72 hours.
  - Usually these hallucinations are visual. In contrast to delirium tremens, it is not associated with clouding of the sensorium.

- **Withdrawal seizures**
    - These seizures **("rum fits")** are generalized tonic-clonic convulsions. These develop usually 12–24 hours after the last drink, but may develop after only 2 hours of abstinence.
    - About 3% of chronic alcoholics develop withdrawal-associated seizures and, about 3% of them may develop status epilepticus.
    - About 30% of patients, who develop delirium tremors, give a history of preceding alcohol withdrawal seizures.
- **Delirium tremens**
    - It usually develops between 24 and 72 hours after the last drink and last for about 1–5 days. If early alcohol withdrawal is not treated, about 5% will progress to delirium tremens.
    - **Clinical features:**
        - These include agitation, visual hallucinations (Lilliputian/macroscopic), illusions, delusions, tachycardia, hypertension, diaphoresis, and dilated pupils.
        - Dehydration may occur as a result of diaphoresis, hyperthermia, vomiting, and tachypnea.
        - **Other features:** Hypokalemia, hypomagnesemia, and hypophosphatemia.
    - Death occurs in about 5% of patients, usually due to arrhythmias, pneumonia, or electrolyte imbalance.

Management of alcohol withdrawal syndrome

- Maintain patent airway and breathing.
- Thiamine 100 mg in 500 mL glucose solution infused intravenously after withdrawing appropriate blood samples since in alcoholics, the thiamine will be depleted and the TPP would not be present as a result, in patients with altered sensorium for prevention of progress to Wernicke Korsakoff psychosis.
- Maintain fluid and electrolyte balance.
- **Mild cases of withdrawal:** Provide supportive care, such as reassurance and nursing care (monitoring of vital sings).
- **Benzodiazepines (nitrazepam, diazepam, and lorazepam):** For patients with moderate to severe withdrawal. They also control seizures.
- **β-blockers:** It may reduce anxiety and tremors.
- **Anticonvulsants:** Such as phenytoin, valproic acid, carbamazepine, and levetiracetam are of little value in treating or preventing alcohol withdrawal seizures.
- **Management of associated conditions:** Such as pneumonia, electrolyte imbalances, GI bleed, liver failure, pancreatitis, neurological injury, and trauma.

Rehabilitation

Aims at relapse prevention by using the pharmacotherapy and psychotherapy.

Drugs used for relapse prevention in alcohol dependence:

- **First-line medications:** Naltrexone and acamprosate
- **Second-line medications:** Disulfiram, topiramate, gabapentin, baclofen, and nalmefene

- **Disulfiram**
    - Disulfiram is **inhibitor of enzyme aldehyde dehydrogenase (ALDH)** and blocks the conversion of acetaldehyde (derived from alcohol) to acetic acid, thus increasing the levels of toxic substance, acetaldehyde in the body.
    - When alcohol is consumed while on disulfiram, acetaldehyde accumulates in tissues and blood and produces distressing symptoms (aldehyde syndrome). These unpleasant symptoms include flushing, burning sensation, throbbing headache, perspiration, uneasiness, palpitations, nausea, postural faintness, and, in some cases, circulatory collapse. Duration of symptoms (1–4 hours) depends on the amount of alcohol consumed.
    - **Side effects:** Infrequent and include rashes, metallic taste, nervousness, and malaise. Very rarely myocardial infarction, congestive heart failure, respiratory depression, convulsions, and death may develop.
    - **Dosage:** Oral 250–500 mg/daily.
- **Naltrexone:**
    - It is an opioid-receptor antagonist. It reduces alcohol craving, number of drinking days, and chances of resumed heavy drinking.
    - **Dose:** Oral 50 mg/day in a single dose.
    - **Side effects:** Nausea decreased appetite, fatigue, and headache.
- **Acamprosate:**
    - It is a weak N-methyl-D-aspartate (NMDA) receptor antagonist with modest GABA A receptor antagonist. It normalizes the dysregulated NMDA-mediated glutamatergic excitation that occurs in alcohol withdrawal and early abstinence. It reduces relapse of the drinking behavior.
    - **Dose:** Oral 666 mg given thrice a day. It is available in 333 mg enteric-coated tablet.
    - **Side effects:** Diarrhea, dizziness, and headache.

EATING DISORDERS

Q. PE6.6 Discuss the common adolescent eating disorders (Anorexia Nervosa, Bulimia).

Etiology: Unknown but probably includes genetic, environmental, psychologic, and cultural factors.

Onset: Average age is 17 years, often associated with emotional stressors, particularly conflicts with parents about independence and sexual conflicts. Very late-onset anorexia nervosa has a poorer prognosis.

Type	***Anorexia nervosa***	***Bulimia nervosa***	***Binge eating disorder***
Symptoms	➢ Avoidance ➢ Binge ➢ Compensation	➢ Binge ➢ Compensation	Binge only
Weight	Underweight	Normal weight	Overweight

Clinical Features

- **Avoidance of high calorie food** and restricted food intake because of intense fear of gaining weight or becoming fat.
- **Compensatory behaviors:** Excessive exercise routine, self-induced vomiting or use of laxatives/diuretics/enemas.
- **Marked weight loss:** Refusal to maintain body weight at or above a minimally normal weight for age and height.
- **Distortion of body image** so that patients regard themselves as fat even when they appear grossly underweight, significant amount of time spent examining and denigrating self for perceived signs of excess weight, great concern with appearance, and denial of emaciated condition.
- In postmenarcheal females, **amenorrhea** (i.e., the absence of at least three consecutive menstrual cycles).
- Excessive interest in food-related activities (other than eating).
- Obsessive-compulsive symptoms and depressive symptoms.

Major Subtypes

- **Restricting type:** Fasting, introverted, decreased risk of substance abuse, family conflict is covert.
- **Bulimic type:** Binge eating or purging, more volatile, family frequently disengaged, prone to substance abuse.

Physical Examination

- **Signs of malnutrition:** Emaciation, hypotension, bradycardia, lanugo (i.e., fine hair on the trunk), and peripheral edema.
- **Signs of purging:** Eroded dental enamel caused by emesis and scarred or scratched hands from self-gagging to induce emesis. Parotid abscess and dental caries—because of keeping food in mouth for long time.
- Evidence of medical conditions due to abnormal diets, starvation, and purging.

Diagnostic Tests

- **Signs of malnutrition:** Normochromic normocytic anemia, abnormal electrolytes, and elevated liver enzymes
- **Signs of purging:** Metabolic alkalosis, hypochloremia, and hypokalemia due to emesis. Metabolic acidosis caused by laxative abuse.
- **Hormonal abnormalities:**
  - Elevated growth hormone and plasma cortisol levels and reduced gonadotropin levels (along with low FSH, LH, estrogen, and testosterone).
  - T3 may be reduced, but T4 and TSH are often normal.
  - Increased corticotrophin CSF levels.

Course and Outcome

- About 20–30% of restricting anorexics eventually develop binge eating within the first 5 years of onset.
- These illnesses have a chronicity of 5–10%.
- Generally favorable outcome is achieved in 60–70% of patients at 5–7-year outcome.
- Long-term mortality rate of individuals hospitalized for anorexia nervosa is 10%, due to the effects of starvation and purging or suicide.

Treatment

- Initial treatment should be correction of significant physiologic consequences of starvation with hospitalization if necessary.
- Behavioral therapy should be initiated, with rewards or punishments based on absolute weight, not on eating behaviors.
- Family therapy designed to reduce conflicts about control by parents.
- Antidepressants when comorbid depression is present.

Bulimia Nervosa

Occurs at 1:9 male-to-female ratio.
Etiology: Psychologic conflict regarding guilt, helplessness, self-control, and body image may be predisposing factor.
Onset: During late adolescence or early adulthood and often follows a period of dieting.

Clinical Features

- Recurrent episodes of **binge eating**
- Obsession with dieting but followed by binge eating of high-calorie foods.
- Absence of self-control over eating during binges.
- Binges are associated with emotional stress and followed by feelings of guilt, self-recrimination and compensatory behaviors.
- Recurrent, inappropriate compensatory behavior: **Self-induced vomiting, purgation** or dieting after binges.
- Self-castigation for mild weight gain or binges. Attempts to conceal binge-eating or purging, or lies about behaviors.
- **Weight maintained** within normal range.

Major Subtypes

- **Purging type:** Self-induced vomiting or use of laxatives, diuretics, or enemas.
- **Nonpurging type:** Use of other compensatory mechanisms, such as fasting or excessive exercise.

Physical Examination

- Calluses on the dorsal surface of their hands (self-induced vomiting), dental erosion and caries, esophageal erosion, lanugo hair, enlarged parotid glands (chipmunk face secondary to increased amylase), bradycardia, hypotension, and arrhythmias (secondary to hypokalemia).
- **Associated problems:** Depression, substance abuse, and impulsivity (kleptomania).
- **Comorbid disorders:** Borderline personality disorder is present in 50% of patients.

Treatment
- Antidepressants (SSRI).
- Cognitive and behavioral therapy.
- Psychodynamic psychotherapies are useful for borderline personality traits.

Diagnostic Tests: Evidence of Laxative or Diuretic Abuse

- ***Course:*** It may be chronic or intermittent.
- ***Outcome:*** Prognosis of bulimia is better than anorexia.
  - Favorable prognostic indicators: Younger age at onset, higher social class, and family history of alcohol abuse.

Differences between anorexia and bulimia are shown in **Table 20.25**.

TABLE 20.25: Differences between anorexia and bulimia.

Anorexia nervosa	*Bulimia nervosa*
➢ Denies abnormal eating behavior	➢ Recognizes abnormal eating behavior
➢ Introverted	➢ Extroverted
➢ Turns away food in order to cope	➢ Turns to food in order to cope
➢ Preoccupation with losing more and more weight	➢ Preoccupation with attaining an "ideal" but often unrealistic weight

SLEEP DISORDERS

Disturbed sleep is one of the most frequent health complaints.

Sleep disorders can be of various types:
- Dyssomnias: Insomnia and hypersomnia
- Parasomnias:
  - NREM parasomnias: Somnambulism, somniloquy, sleep terrors, and bruxism (teeth grinding)
  - REM parasomnias: Night mares, REM behavioral disorder
- Narcolepsy, Kleine Levin syndrome
- Circadian rhythm disorders
- Sleep-related movement disorders: RLS and PLMD
- Obstructive sleep apnea, upper airway resistance syndrome

Major categories of sleep disorders as per DSM IV:
- **Dyssomnias:** Sleeping disorder that makes it difficult to get to sleep, or to stay sleeping.
- **Parasomnias**
- **Neurological/psychiatric disorders**

Insomnia

Insomnia is the complaint of ***inability to sleep*** long enough or maintain sleep despite the patient having adequate amount of time to devote to sleep. It is associated with impairment of daytime functioning or mood symptoms.

Insomnia can be classified according to the nature of sleep disruption and the duration of the complaint. Most insomnia patients present with two or more of these symptoms:

- **Sleep onset insomnia:** Difficulty falling asleep.
- **Sleep maintenance insomnia:** Frequent or sustained awakenings.
- **Sleep offset insomnia:** Early morning awakenings or frequent nocturnal awakenings.

Common causes of insomnia

Primary sleep disorders:

- Idiopathic insomnia
- Periodic leg movements
- Restless legs syndrome

Secondary sleep disorders:

- **Psychiatric or psychological problems:** Mood disorders (e.g., mania, depressive, and anxiety disorders); delirium and dementia
- **Use or misuse of drug/substance abuse:** Consumption or discontinuation of drugs/substances. Withdrawal of addictive drug (e.g., alcohol and benzodiazepines); stimulant drugs (e.g., caffeine, nicotine, and amphetamines); prescribed drugs (corticosteroids and dopamine agonists)
- **Physical/medical disorders:** Chronic pain (e.g., carpal tunnel syndrome); nocturia (e.g., prostatism); malnutrition, chronic obstructive pulmonary disease, asthma, menopause, and neurologic disorders.

Consequences

- Depression may cause insomnia, and insomnia may cause depression.
- Can heighten the perception of pain.
- May be associated with:
  - Development of endocrine disturbances.
  - Increased risk for hypertension or cardiovascular disease.
  - Increased risk for motor vehicle accidents and occupational errors.

Treatment

- **Behavioral therapy** is effective but may be time-consuming. These include: Relaxation techniques and cognitive behavior therapy.
- Other measures include: Decreasing alcohol intake, to have early supper, daily exercise, and hot bath prior to going to bed and routine going to bed at the same time.
- **Pharmacologic treatment:**
  - Benzodiazepines (e.g., temazepam, triazolam, estazolam, and eszopiclone) for sleep-maintenance insomnia.
  - Nonbenzodiazepines (e.g., zolpidem, zolpidem-controlled release zaleplon, zopiclone or eszopiclone) for both sleep-onset and sleep-maintenance insomnia.
  - Melatonin agonist (e.g., ramelteon) for sleep onset insomnia.
  - Antihistamines (e.g., diphenhydramine and promethazine) and antidepressants (e.g., amitriptyline, trimipramine, trazodone, and mirtazapine).

Parasomnias

It consists of various uncommon disruptive sleep-related disorders with abnormal unpleasant or undesirable behaviors or experiences that occur during sleep, entry to sleep, or arousal from sleep **(Table 20.26)**.

TABLE 20.26: Types and features of parasomnias.

NREM sleep-associated parasomnias	
Confusional arousals	Sudden arousals, associated with confusion and disorientation
Sleep terrors	Sudden arousal with fearful agitated behavior, often with screaming or crying; patient may be disoriented, unresponsive to the environment and typically do not remember the event afterward
Sleepwalking	Arousal with complex motor behavior, walking, running, talking, and eating
Others	Somniloquy (sleep talking), bruxism (teeth grinding)
REM sleep-associated parasomnias	
Nightmare disorder	Recurrent, disturbing dreams not associated with autonomic activity or amnesia
REM sleep behavior disorder (RBD)	Abnormal persistence of muscle tone during REM sleep, permitting vigorous movements while dreaming. Also includes screaming, punching, and kicking for up to several minutes, sometimes resulting in injury to the patient or bed partner

Treatment

- **Avoid:** Caffeine or alcohol and drugs, such as serotonin reuptake inhibitors and MAO inhibitors.
- **Remove dangerous objects** from the environment of sleep.

- **Pharmacologic therapy:** These include clonazepam, tricyclic antidepressants, dopamine agonists or levodopa, melatonin, and carbamazepine.

NARCOLEPSY

Etiology

- Loss of orexin (hypocretin) signaling
- Strong genetic/HLA association: HLADQB1*0602 haplotype is present in 95% of patients with cataplexy and in 96% of those with orexin deficiency.

Clinical Features

The classic "narcolepsy tetrad" consists of four main clinical features:

1. **Excessive daytime sleepiness (EDS)** occurring almost daily for at least 3 months that interferes with functioning **plus three specific symptoms** related to an intrusion of REM sleep characteristics. Sleep attack is the most common symptom.
2. **Cataplexy** (*pathognomonic sign*): Sudden weakness or loss of muscle tone without loss of consciousness, usually precipitated by loud noise, laughter, or other intense emotions.
3. **Hypnagogic/hypnopompic hallucinations: Hypnagogic hallucinations** (hallucinations occur as the patient is going to sleep) or **hypnopompic hallucinations** (hallucinations upon awakening).
4. **Sleep paralysis:** Muscle paralysis upon awakening. It consists of episodes up to several minutes in duration of inability to move and occasionally feeling unable to breathe despite being awake. Fragmented sleep is classically seen in patients.

Diagnosis

- **Electrographic evidence/multiple sleep latency test:** Demonstration of rapid transition from wakefulness to sleep and shortened REM sleep onset is confirmatory for the diagnosis. A mean sleep latency of ≤8 minutes and two or more sleep onset REM periods (SOREMPs) on a multiple sleep latency test (MSLT) is performed using standard techniques.
- HLA testing may also be useful.
- Cerebrospinal fluid (CSF) hypocretin-1 concentration is low.

Treatment

Mainly symptomatic: Forced naps at a regular time of day is usually the treatment of choice.

Psychostimulants:

- **Wake-promoting therapeutics: Modafinil** is the drug of choice, principally because it has few side effects and has low addiction potential. Older drugs such as methylphenidate or methamphetamine or dextroamphetamine are used as alternatives, particularly in refractory patients.
- **Tricyclic antidepressants (TCAs)** help to suppress the REM sleep (e.g., protriptyline, imipramine, and clomipramine) or the selective serotonin reuptake inhibitors (SSRIs) [e.g., fluoxetine (10–20 mg/d)] or selective norepinephrine reuptake inhibitors (e.g., venlafaxine) can improve cataplexy.
- **Gamma hydroxybutyrate (GHB)** is effective in reducing daytime cataplectic episodes.
- **Sodium oxybate,** a sodium salt of GHB alone or combined with modafinil, can reduce sleep disruption significantly. It is administered at night to help consolidate REM sleep and increase slow-wave sleep. It significantly reduces daytime sleepiness and also improves cataplexy.
- **Pitolisant**, a histamine H3 receptor inverse agonist, is effective treatment for cataplexy and daytime sleepiness.
- Others: Selegiline, clomipramine, fluoxetine, and venlafaxine.

Circadian Rhythm Sleep Disorders

- Circadian rhythm sleep disorders (CRSDs) are mainly due to alterations of the circadian time-keeping system or asynchrony between the endogenous circadian rhythm and external factors that affect the timing or duration of sleep.
- Wake-sleep schedule disorders fall into two categories:
    1. Primary malfunction of the biologic clock per se
    2. Secondary malfunction due to environmental effects on the underlying clock.

Example: Shift work type: Night shift or shift changes

Jet Lag Disorder is associated with excessive daytime sleepiness, sleep onset insomnia, and frequent arousals from sleep, especially in the latter half of the night. Transient symptoms of difficulty falling asleep at the appropriate time and daytime sleepiness following rapid change in time zones altering the timing of exogenous light stimuli.

Diagnosis

- Made by **history** and a **sleep diaries**.
- **Actigraphy:** Based on a wrist-mounted motion detector worn as an outpatient for at least 7 days. It can help in quantify time spent asleep.

Treatment of the Primary Circadian Rhythm Disorders

- **Chronotherapy:**
  - Useful in delayed sleep phase type of circadian rhythm disorders.
  - Patient delays the onset of sleep by a few hours every day and sleeps only the predetermined number of hours until the onset of sleep occurs at the desired time.
- **Phototherapy:** Bright light therapy:
  - Patient sits at a prescribed distance from a bright light with an illuminance of >2,500 lux at that distance for 2–3 hours in the morning.
- **Pharmacologic therapy:**
  - **Melatonin** 3 mg given 4–5 hours before the desired time of sleep onset. Useful in patients with delayed sleep phase.
- **For jet lag:**
  - Behavioral strategies (good sleep hygiene), shifting sleep, and wake times gradually before travel to conform to the destination's time zone and avoiding bright light exposure before bedtime.
  - Melatonin administered before bedtime in the new time zone.

Sleep-related Movement Disorders

These include restless leg syndrome and periodic limb movement disorder.

Restless Leg Syndrome (Willis-Ekbom Disease)

It is characterized by urge to move legs and patient usually complains of a variety of uncomfortable sensations in the legs (e.g., pins and needles, creeping or crawling sensations, aching, itching, stabbing, heaviness, tension, burning, or coldness).

- Symptoms are usually experienced during periods of prolonged rest or inactivity.
- Symptoms are typically relieved only by movement or stimulation of the legs.
- The discomfort appears more prominent during evening and between midnight and 4 AM.
- May disrupt sleep initiation.

Types

- **Primary or idiopathic:** Inherited as an autosomal dominant disorder.
- **Secondary:** To other causes, including **iron deficiency**, pregnancy, varicose vein or venous reflux, uremia, or folate deficiency, peripheral neuropathy, radiculopathy rheumatoid arthritis, etc. It often develops suddenly and may be daily from the very beginning.

Treatment

- Treatment of the underlying condition.
- **First-line drugs:** Dopamine agonists (e.g., pramipexole, carbidopa/levodopa or pergolide, and ropinirole) are the treatments of choice.
- **Other drugs** include quinine levodopa preparations, gabapentin, opiate agonists (e.g., oxycodone, codeine, propoxyphene oxycodone, or methadone), benzodiazepines (e.g., clonazepam which often assists in staying asleep and reducing awakenings from the movements) may also be effective. Anticonvulsants, such as gabapentin, often helpful in patients with painful sensations.

Periodic Limb Movement Disorder

- It is a repetitive, stereotyped limb movement and consists of 0.5- to 5.0-s extensions of the great toe and dorsiflexion of the foot.
- It occurs/recurs every 20–40 seconds during NREM sleep and each episode lasts from minutes to hours.
- Movements often disrupt sleep and lead to daytime sleepiness.

Treatment

Dopaminergic medications or benzodiazepines.

PSYCHOSEXUAL AND GENDER IDENTITY DISORDERS

Q. PS13.1, 13.2 and 13.4 **Enumerate and describe the magnitude and etiology of psychosexual and gender identity disorders.**

It includes sexual dysfunction, paraphilia, and gender identity disorder.

Sexual Dysfunctions: Based on Phases of Sexual Cycle

- ***Desire disorders:***
    - Decreased—frigidity/hypoactive sexual desire disorder
    - Increased—satyriasis (male), nymphomaniac (female)
- ***Arousal disorders:*** Erectile dysfunction (organic/psychological), female sexual arousal disorder
- ***Orgasm disorders:*** Premature ejaculation, female orgasm disorder
- ***Resolution disorders:*** Post-coital dysphoria

Paraphilias

See **Table 20.27.**

TABLE 20.27: Paraphilia—abnormality in sexual preference.

Deviation in sexual act: Sexual pleasure attained by	***Deviation in sexual object***	
	Animate	***Inanimate***
➢ ***Sadism***—inflicting pain on others ➢ ***Masochism***—feeling pain inflicted by partner ➢ ***Voyeurism***—watching others grooming/getting intimate ➢ ***Exhibitionism***—showing private parts to unexpecting individual ➢ ***Frotteurism***—rubbing genitals against clothed individual	➢ ***Pedophilia***—child ➢ ***Bestiality/ zoophilia***—animal ➢ ***Necrophilia***—cadavers	➢ ***Fetishism***—shoes, stockings, etc. ➢ ***Transvestite fetishism***—cross dress *for sexual pleasure*

Gender Identity Disorders (DSM-IV)

- It has been renamed as gender dysphoria in DSM-5 and as gender incongruence in ICD-11.
- ICD-11 considers gender identity disorder as a sexual health disorder and not a psychiatric disorder.
- It refers to presence of incongruence/dissatisfaction with allotted/biological sex + persistent desire to be identified as member of opposite sex.
- It can be further classified as:
    - Transexualism is the severe form and they can be offered sex reassignment surgery along with hormonal therapy.
    - Removal of male external genitalia and reconstruction of female external genitalia and vice-versa is the procedure followed in sex reassignment surgery.

Feature	***Dual role transvestism***	***Transexualism***
Cross dressing *to be identified as member of opposite sex*	Present	Present
Desire for sex change therapy	Absent	Present

PERSONALITY DISORDERS

Q. PS11.1, 11.2 and 11.4 **Enumerate clinical features and management of personality disorders.**

Personality: Enduring pattern of behavior, cognition, and emotions that makes every individual unique.
Personality disorder: Problems with understanding self and others, thus causing interpersonal dysfunction **(Table 20.28)**.

TABLE 20.28: Classification of personality disorders (DSM-5) and their characteristic features.

Cluster A ***Odd, eccentric***	***Cluster B*** ***Dramatic, emotional***	***Cluster C*** ***Anxious, fearful***
➢ ***Schizoid*** (emotionally detached) ➢ ***Schizotypal*** (magical thinking, speech oddities) ➢ ***Paranoid*** (extreme suspiciousness)	➢ ***Borderline*** (unstable relationships, mood swings) ➢ ***Histrionic*** (need to center of attraction) ➢ ***Narcissistic*** (self-centered) ➢ ***Antisocial*** (break rules and laws)	➢ ***Anxious-avoidant*** (sensitive to rejection) ➢ ***Dependent*** (need reassurance) ➢ ***Anankastic*** (perfectionist)

Management of personality disorders includes both pharmacological methods (like antidepressants, antipsychotics and mood stabilizers) as well as psychotherapy. Dialectic behavior therapy is used for borderline personality disorder.

CHILD PSYCHIATRY

Q. PS14.1, 14.2 **Enumerate psychiatric disorders occurring in childhood and adolescence.**

It includes the following disorders:

- Neurodevelopmental disorders: Intellectual disability, specific learning disability
- Disruptive behavioral disorders of childhood: Oppositional defiant disorder, conduct disorder
- ADHD, Tourette's syndrome
- Autism spectrum disorders
- Disruptive mood dysregulation disorder

Disruptive Behavioral Disorders of Childhood

See **Table 20.29**.

TABLE 20.29: Disruptive behavioral disorders of childhood.

Features	***Oppositional defiant disorder***	***Conduct disorder***
Angry, irritable, and revengeful	Present	Present
Disobedient behavior, out of keeping with child's developmental age	Persistent ≥6 months	Persistent ≥12 months
Abusive behavior	Verbal	Verbal and physical
Violation of others rights (theft, destruction of property, fire setting, and torturing animals)	Usually not seen	Present

ATTENTION DEFICIT HYPERACTIVITY DISORDER

- It is a disorder characterized by triad of hyperactivity, impulsivity, attention deficit manifesting at ≥2 contexts and having its onset before 12 years of age. It is more common in boys.
- Etiology: Abnormality in information processing due to involvement of cortico-striatal-thalamo-cortical loop
- Clinical features include—inability to wait for their turn or to sit at one place, poor concentration, losing things easily, poor scholastic performance despite normal IQ, etc.
- Management includes pharmacotherapy stimulants like methylphenidate and dextroamphetamine and nonstimulants like atomoxetine, clonidine, and behavioral techniques like attention enhancing tasks, social skills training, and behavior therapy.

Tic/Tourette Disorder

- Tourette syndrome (TS) is a neurological disorder characterized by repetitive, stereotyped, involuntary movements and vocalizations called tics.
- It can be of four types:
  1. Vocal tics: Throat clearing, grunting
  2. Motor tics: Eye blinking, head nodding
  3. Coprolalia: Blurting obscene words
  4. Palilalia: Repeating words
- It can be managed by using antipsychotics like risperidone and haloperidol. Clonidine can also be used.
- Behavioral techniques include habit reversal and others.

AUTISTIC SPECTRUM DISORDER

- It was previously called pervasive developmental disorders to describe a group of disorders that shared similar clinical features (i.e., abnormalities in reciprocal communication and repetitive stereotyped behaviors as core features).
- Clinical features include self-absorbed child with poor eye to eye contact, lack of social smile, delayed milestones, problems in attachment with parents and others, repetitive hand wringing, banging, etc.
- Management is mainly with psychotherapy (social skills training, speech and communication, behavioral) and antipsychotics like risperidone and aripiprazole.

Childhood Depression

- It can also be called as anaclitic depression.
- Clinical features differ from that in adults that it can present with school refusal, frequent anger outburst, and recurrent somatic complaints.
- Fluoxetine is the antidepressant approved for use.

Disruptive Mood Dysregulation Syndrome

- Characterized by presence of temper outbursts which can be expressed verbally/physically, are out of keeping with the situation and in excess than that expected for child's developmental age.
- Seen in children of age 6–18 years
- Temper outbursts occur ≥3 times/week for at least 12 months, in at least two different settings (school, home, etc.)
- Management is with pharmacotherapy (SSRI, stimulants, etc.) and psychotherapy (CBT).

INTELLECTUAL DISABILITY

Q. **PS15.1** **Describe the etiology and magnitude of mental retardation.**

Q. **PS15.2** **Describe and discuss intelligence quotient and its measurement.**

- It was called mental retardation in ICD-10. It has been renamed as intellectual disability in DSM-5 and ICD-11 calls it disorders of intellectual development.
- Normal intelligence is defined as: IQ 90–110
- Dull normal intelligence: IQ 80–89
- Borderline intelligence: IQ 70–79

Table 20.30 shows the classification based on severity of intellectual disability.

TABLE 20.30: Classification based on severity of intellectual disability.

Feature	*ICD10*	*ICD11/DSM-5*
Severity assessed by	Intelligence quotient	Adaptive functioning
Mild	50–69	2–3 SD below mean
Moderate	35–49	3–4 SD below mean
Severe	20–34	>4 SD below mean
Profound	<20	

Etiology

Genetic disorders like Down syndrome and Fragile X syndrome are the most common causes of intellectual disability. Other causes include metabolic and chromosomal disorders, obstetric complications, and nutritional and infective causes.

Clinical Features

These include physical stigmata of respective chromosomal anomaly like wide spaced eyes, microcephaly, short stature, etc., slow to learn, below average intelligence.

Investigations

- Blood and urine work up to look for inborn errors of metabolism
- Neuroimaging and karyotyping to establish the cause of ID
- Intelligence assessment

Management

It includes behavior therapies like contingency management, life skills training, use of antipsychotics to control aggression, etc.

Specific learning disability includes:
- **Dyslexia:** Difficulty in reading
- **Dysgraphia:** Difficulty in writing
- **Dyscalculia:** Difficulty in arithmetics.

Management: Training with the help of special educator

Treatment modalities
- Behavior management
- Environmental supervision
- Monitoring the child's development needs and problems
- Programs that maximize speech, language, cognitive, psychomotor, social, self-care, and occupational skills
- Ongoing evaluation for overlapping psychiatric disorders, such as depression, bipolar disorder, and ADHD
- Family therapy to help parents develop coping skills and deal with guilt or anger
- Early intervention programs for children younger than 3 with mental retardation
  - Provide day schools to train the child in basic skills, such as bathing and feeding
  - Vocational training

GERIATRIC PSYCHIATRY

Q. PS16.1, 16.2 and 16.4 Describe common psychiatric disorders in the elderly.

- All the psychiatric disorders can occur in the elderly too.
- They might vary in their presentation due to significant overlap of symptoms of dementia and other medical comorbidities.
- Due to altered bodily response of the drug, management of the illness varies from adult psychiatry.
- Common psychiatric disorders in elderly are:
  - Dementia: Described above
  - Geriatric depression/melancholic depression (described under depression): Sertraline may be beneficial especially in those with cardiac comorbidities.
  - Old age psychosis: Features of late-onset schizophrenia may be seen including paranoid ideations.
- Management depends on management of comorbidities, avoid polypharmacy, adequate palliative care, slower titration of drug dosage, active watch for side-effects, and supportive psychotherapy.

PUERPERAL DISORDERS

Three common psychiatric disorders occur after childbirth.

1. **Postpartum blues:** These are characterized by irritability, labile mood, and tearfulness. Symptoms start soon after childbirth, and peak by about the fourth day and then resolve.
2. **Postpartum depression:** It develops in 10–15% of women within a month of delivery and is characterized by guilt, anhedonia, and suicidal thoughts. It is managed with antidepressants, ECT.
3. **Puerperal psychosis**
   - It is a rare disorder occurring in perhaps <1 or 2 per 1,000 deliveries. It is more common in primiparous than multiparous women.

- Symptoms generally appear abruptly within about 3 days to several weeks after delivery.
- Rarely serious complication, such as a manic or depressive psychosis may develop. It may be associated with a personal or familial history of bipolar disorder.
- Management is with antidepressants, antipsychotics, and ECT.
- Hospitalization is generally indicated.
- Most women recover but have an increased (25%) risk of developing puerperal psychosis in the next pregnancy, and a 50% lifetime risk.

EMERGENCIES IN PSYCHIATRY

Q. PS17.1, 17.2 and 17.3 Enumerate and describe the recognition and clinical presentation of psychiatric emergencies. Describe the initial stabilization and management of psychiatric emergencies.

It can be broadly classified as behaviors manifesting with harm to self/others, acute effects of substance use, and acute psychosis/mania.

Suicide, Deliberate Self Harm

- It is an act leading to intentional death.
- September 10 is observed as World Suicide Prevention Day by WHO and International Association for suicide prevention as an awareness creating tool regarding the preventability of suicide.
- Suicide has become one of the leading causes of preventable deaths.
- Mental Health Care Act, 2017 has decriminalized suicide by stating that any individual committing suicide shall be presumed to be under severe stress, unless proven otherwise.

Emil Durkheim described three ***types of suicide:***

1. Egoistic: Due to lack of integration into society (e.g., person with poor support committing suicide)
2. Altruistic: Due to excessive integration into society (e.g., committing suicide for the sake of a celebrity)
3. Anomic: Due to rejection of integration into society (e.g., committing suicide due to debts)

Risk Factors

- Middle-aged men
- Poor family and social support
- Single/unmarried/divorced
- Recent loss in relationship, occupation, and finance
- Medical comorbidities: Long-standing illness, end-stage diseases
- Psychiatric comorbidities: Depression, substance use, and schizophrenia
- Previous suicide attempt
- Family history of suicide
- Postmortem studies have found low-levels of 5-hydroxyindoleacetic acid in those who completed suicide

Early warning signs of suicidal intent:

- Writing a suicide note
- Making a will
- Transferring money to the account of family member
- Transferring one's responsibility
- Indicating that this is my last visit and after this all the problems will be solved
- Procuring/collecting harmful substances (gun, knife, and insecticides)
- Visiting the site to inspect and find out the timings when human traffic will be lower
- Expressing feelings of hopelessness, worthlessness
- Indulging in harmful behavior: Driving with high speeds, excessive substance intake

Management

- Suicidal risk assessment: Assess for risk factors and early warning signs. Hopelessness carries a high risk
- IP care is advisable for an individual with high suicidal risk.
- 24-hour supervision while ensuring a safe environment (keep away any objects that can be used to harm oneself).
- Complete diagnostic evaluation for medical and psychiatric comorbidities and their management.
- Clozapine and lithium are the two drugs with antisuicidal properties.
- Antidepressants and mood stabilizers can be used in comorbid depressive disorder.
- Intranasal/IV Esketamine/ECT also has been used for rapid control of symptoms
- Provision of psychological and emotional support through supportive, cognitive behavioral psychotherapy, and family therapy

Acute Agitation

Agitation refers to a state of sudden behavioral activation. It can occur as a symptom of psychiatric disorders (mania, substance intoxication/withdrawal), depression, schizophrenia, dissociative disorders or due to organic causes (delirium, catastrophic reaction in dementia, and head injury).

Management includes:
- Evaluation for organic causes
- Ensure safety of patient and the examiner: Examination in open room which is free of objects that can be used to harm.
- Oral/IV drugs: Benzodiazepines (lorazepam and diazepam) and antipsychotics (haloperidol)
- Use of physical restraints if required
- Monitoring vitals and detailed evaluation once the patient is calm.

COMMUNITY PSYCHIATRY

Q. PS19.1 Describe the objectives strategies and contents of the National Mental Health Programme (NMHP), 1982.

Objectives

- To ensure availability and accessibility of minimum mental healthcare for all in foreseeable future, particularly to most vulnerable and underprivileged section of population.
- Encourage application of mental health knowledge in general healthcare and social development.
- Promote community participation in mental health service development and stimulate efforts toward self-help in community.

Strategies

- Integration of mental healthcare with primary healthcare (training PHC doctors in diagnosis and treatment of common psychiatric disorders like depression and insomnia).
- Strengthening tertiary care institutions for treatment of mental health disorders.
- Eradicating stigmatization of mentally ill patients (through awareness campaigns) and protecting their rights through regulatory institutions like central and state mental health authorities.
- NMHP is implemented through District Mental Health Program (DMHP) and School Mental Health Program (SMHP).
- Activities in ***District Mental Health Program:***
  - Training of medical, paramedical personnel, and community leaders
  - Community mental healthcare through existing infrastructure of health services
  - Information, education, and communication activities
- Activities in ***School Mental Health Program:*** Training school teachers by providing:
  - Knowledge and skills to identify emotional, conduct in students
  - System to refer students with psychological problems to DMHP team for evaluation and treatment
  - Skills to promote life skills among students

FORENSIC PSYCHIATRY

Q. PS19.3 Describe and discuss the basic legal and ethical issues in psychiatry.

Confidentiality in Psychiatry

- Mental healthcare professional has the duty to maintain confidentiality with respect to information providing during diagnosis and treatment of mental illness.
- However, maintaining confidentiality is exempted when the information is required for treatment, in legal issues, to prevent harm to others or for public safety.

Criminal Responsibility of Mentally Ill

- If the act occurred as a product of mental illness, individual with mental illness in not criminally responsible, if at the time of committing the act he was unable to understand the nature and consequences of the act or that the act is wrong or contrary to law. This is also called the insanity defense.
- McNaghten's rule states that unless proven otherwise, every person shall be considered to be of sane mind which shall be decided by the jury.

- Insanity is punishable if he was of sound mind at the time of committing the act (i.e., during lucid interval, remission phase of episodic illness)
- Acts committed under intoxication of substance/hypnotization cannot stand for legal defense as the person was aware of the consequences while initiating the act.

Civil Responsibility of Mentally Ill

- During lucid intervals of psychiatric disorder when he is able to understand the consequences of the act, one can exercise his civil rights of making a will to dispose one's assets, to give witness, and also can make a contract. However, these are subject to courts discretion.
- Individual with profound intellectual disability/dementia cannot hold a driving license.
- A marriage shall be void and eligible for divorce if at the time of marriage, either of the party was incapable of giving valid consent or has been suffering from such severity of illness that interferes with usual course of marriage and procreation.

Q. PS19.2 Describe the salient features of Mental Health Care Act, 2017.

It has replaced the Mental Health Care (MHC) bill of 2013, wherein previous assurance-based approach has been changed to right-based approach. Its main features include:

- It recognizes the rights of mentally ill by recognizing capacity of individual to make mental healthcare decisions, making regulations for hospitalization (independent and supported), and use of restraints.
- Advanced directive: An individual has the right to choose how he wants to be treated for mental illness.
- Nominated representative: Every individual can appoint his representative who would take decisions on his behalf in case he loses his capacity to make mental health decisions.
- Central and state mental health authorities to protect the rights of mentally ill.
- Decriminalizing suicide: Any person attempting suicide shall be presumed to be under severe stress and hence should not be punished.
- Prohibition of ECT in minors and prohibition of direct ECT
- Rules for establishing Mental Health Establishments

POCSO: Prevention of Children from Sexual Offences Act, 2012 has been framed to protect the child from such offenses.

- Penetrative and aggravated penetrative sexual assault have a punishment of minimum 10 and 20 years life imprisonment + fine, respectively, whereas sexual assault and aggravated sexual assault have a punishment of fine + imprisonment for 3–5 years and 5–7 years, respectively.
- Abuse is defined by tissue damage, neglect, sexual exploitation, and mental cruelty.
- Child abuse is mandatorily reportable offense.
- Treating physician will be charged for criminal offense if not reported.
- Duties of treating physician include: To report the offense and to protect the child
- Clinical features that should raise the index of suspicion: Broken bones in 1st year of life, STD in young children, soft tissue injuries, and nonaccidental burns.

MISCELLANEOUS TOPICS

Q. PS19.5 Describe the concept and principles of preventive psychiatry and mental health promotion (positive mental health); and community education.

Positive Mental Health

It refers to the science and art of **preventing disease, prolonging life and promoting health and well-being,** through organized efforts of society using a whole systems approach + targeted actions for vulnerable groups

- It aims at enhancing behavioral and mental wellness
- **Targets/outcomes** of positive mental health: Well-being, low perceived stress, successful psychological ageing, posttraumatic growth, recover and prevention of mental illness
- Achieved by enhancing **positive psychosocial factors (PPSFs),** which can be individual or environmental
- **Individual PPSFs:** Resilience, optimism, personal mastery, coping self-efficacy, wisdom, spirituality and religiosity, social engagement
- **Environmental PPSFs:** Social support, family dynamics, access to quality healthcare, adequate nutrition and means for physical, cognitive and social activities
- **Interventions aimed at promoting positive mental health:**
    - **Physical exercise:** CDC recommendation for adults: 3–5 days/week of moderate intensity exercise for ≥30 minutes; stretching every day; strength-building activities 2–3 days/week

- **Proper diet and nutrition (Low-risk diet):** PUFA > saturated fats, high in (cereal fiber, marine FA, multivitamins), low in glycemic load and trans fats
- **Sleep hygiene** techniques

Preventive Psychiatry

- ***Aims at the reduction of mental disorders and behavioral problems by:***
  - Early identification of risk and protective factors, and
  - Modifying risk factors with evidence-based interventions for at risk and susceptible population
- ***General principles for effective prevention programs:***
  - Reverse or reduce risk factors, enhance protective factors and address causal factors
  - Increase competency in multiple domains with effective intersectoral linkages
  - Age specific, developmentally appropriate, culturally sensitive
- **Primary prevention** aims at reducing the incidence of disease, three types:
  1. **Universal:** Targeted at the general public and whole population group that has not been identified on the basis of increased risk.
  2. **Selective:** Targets individuals or subgroups of the population whose risk of developing a mental disorder is significantly higher than average, as evidenced by biological, psychological, or social risk factors.
  3. **Indicated:** Targets high-risk persons who are identified as:
     - having minimal but detectable signs or symptoms foreshadowing mental disorder or
     - biological markers indicating predisposition for mental disorder but who do not meet diagnostic criteria for disorder at that time
- ***Evidence-based wide interventions for promotion of well-being and prevention of mental illness***
  - Interventions to improve parental health
  - Preschool and early mental health education
  - School-based mental health promotion and mental illness prevention
  - Prevention of violence, abuse and suicide
  - Alcohol, smoking and substance misuse reduction and prevention
  - Early intervention for mental illness
  - Promoting healthy workplaces
  - Addressing social inequalities, enhancing social cohesion and promotion of housing interventions
  - Reducing stigma and discrimination
  - Positive mental health and recovery from mental illness

Q. PS19.6 Enumerate and describe the identifying features and the principles of participatory management of mental illness occurring during and after disasters.

- Disaster, not only disrupts the quality of life but also creates a significant burden of mental health conditions on an individual and the community.
- Psychological symptoms like anxiety, reactions to trauma and stress and emotional instability other are commonly noted after a disaster, thus having a massive impact on the concerned individual and also on communities.
- Most affected individuals recover with time, with the help of effective postintervention techniques and their individual strengths such as resilience. And in some cases, recovery is incomplete leading to a number of persistent psychotic symptoms which are often severe in nature.
- PTSD is the most frequently encountered along with anxiety, depression and other behavioral and psychological abnormalities. PTSD often comorbid with a variety of psychiatric symptoms like unnecessary fear, hopelessness, worthlessness and helplessness and other physical symptoms which leads to the deterioration of their mental health.
- There are a number of factors affecting different groups of population in their adaptability. Awareness about the importance of postintervention techniques and their applicability in the affected population helps the victims in their recovery.
- Disaster management is a continuous and integrated cyclical process of planning, organizing, coordinating and implementing measures to prevent and to manage disaster effectively.
- **6 'R's of disaster mental health:** Readiness (preparedness), Response (immediate action), Relief (sustained rescue work), Rehabilitation (long-term remedial measures using community resources), Recovery (returning to normalcy) and Resilience (fostering).
- The psycho-social education (cognitive behavioral therapy and psychological first aid) and clinical interventions provide better outcomes.

Learning

Q. Explain the process and theories of learning.

Q. PS2.3 Define and describe the principles and components of learning memory and emotions.

Learning refers to any relatively permanent change in behavior that occurs as a result of practice or experience.

Process of learning has:

- **Motive/Drive:** Dynamic force that energizes behavior and compels an individual to act.
- **Goal:** A definite goal makes learning purposeful and interesting.
- **Barrier/obstacle** in the process of learning

A. **Behavioral theories of learning:** Focuses on objectively observable aspect of learning.
   - ***Ivan Pavlov's*** classical conditioning (learning through association) using dog experiment:
     - Neutral stimulus (bell) + Unconditioned stimulus (food) = Unconditioned response (drool)
     - After conditioning, neutral stimulus becomes conditioned stimulus to produce conditioned response (drool).
   - ***Skinner's*** operant conditioning (learning by re-inforcement/punishment) using rats and pigeons:
     - Animal placed in operant chamber/skinner's box was delivered food on doing a desired task, whereas shock was delivered on doing undesired task. This was used to describe the effect of reinforcement and punishment on behavioral change.

B. **Cognitive and constructive theories of learning:** Looks beyond behavior (i.e. brain-based learning, active construction of new ideas or concepts)
   - ***Menzel***'s experiment with **4 chimpanzees:**
     - An experimenter picked up one of the chimps and carried it around the field while another experimenter hid food tidbits in 18 places while the chimp watched. Later, all four chimps were asked to search for hidden food.
     - Experimental chimp ran directly to the nearby hidden places to find the food, without wandering around in haphazardly like the other three chimps
     - Theorists concluded that individuals develop cognitive maps of the environment and these cognitive maps form the basis for one's perceptions and expectations
   - ***Kohler*'s insight learning:**
     - A food morsel was placed outside the cage at a distance too far for the chimp to reach
     - A short stick was placed inside the cage with another longer stick placed outside
     - After some trial and error, chimp used the short stick to rake in the longer stick and then the food
     - Theorists concluded that learning occurs when solution comes suddenly after a period during which various response strategies are tried
   - ***Albert Bandura*'s** Bobo doll experiment to demonstrate social-cognitive learning
     - **Two groups of children:** Each group shown adults (models) behaving aggressively and nonaggressively, respectively, towards a Bobo doll.
     - Afterwards, children were led into a room in which they could play with many different toys
     - 1st group of children was shown to display more aggressive behavior towards the Bobo doll than 2nd group of children
     - Learning occurs by observing others' behavior and its consequences through modeling
   - ***Jean Piaget***'s learning by assimilation and accommodation
     - **Assimilation:** New ideas are incorporated with their association with known ideas
     - **Accommodation:** If new ideas are different from what is already known, individuals give up former beliefs or substantially change their frame of reference or they do both leading to paradigm shift.
   - ***Kurt Lewin's* Gestalt theory:**
     - Human's selectively perceive and react to complex patterns of stimuli as wholes, not a disconnected parts. This total pattern of stimuli determines what a person perceives and learns
     - Individuals examine their *life space (psychological field unique to each individual)* and the interplay of forces within it (people, material objects, goals, private thoughts etc.)
     - Learning occurs as a result of individuals change in psychological interpretation or change in internal needs of individual

Q. Explain memory and its theories.

Memory is a process by which information is registered, retained in the brain, retrieved and recalled.

Anatomical correlates of memory

- Prefrontal cortex *stores* of short term memories
- Frontal lobe *stores* semantic and episodic memories
- Motor cortex and cerebellum *store* procedural memories
- **Temporal lobe:** *Processing* of new short-term memory *and formation and storage* of long-term semantic and episodic memories
- **Hippocampus:** *Formation* of new long-term semantic and episodic memories
- **Amygdala:** *Formation* of new emotional memories

A. Theories of **General Memory Function** involves following processes:
   - ***Encoding:*** Received sensory input is transformed into a code for storage
   - ***Storage*** of encoded information into memory; short-term (lasts 20–30s without rehearsal) and long-term
   - ***Retrieval:*** Gaining access to stored, coded information process

B. **Atkinson, Shiffrin and Slavin's information processing theory:** Three components
   1. ***Sensory register:*** Registering sensory information which can may be internal or external (via five sense organs)
      - Unattended information is lost; paying attention shifts information from sensory register to working memory
   2. ***Working memory:*** Processing the registered information based on past experiences, motivation, culture etc.
      - Processing involves rehearsal/repetition to retain the information, associating with other information, organizing for storage or discarding it.
      - Information rehearsed/repeated more gets transferred to long-term memory
   3. ***Long-term memory:*** Storing and retrieving the information. It can be further classified as:
      - **Explicit/Declarative memory:** It requires to be consciously recalled. It can be further classified into episodic/autobiographical memory (events in personal experience) and semantic memory (vocabulary, concepts, facts etc.)
      - **Implicit/Nondeclarative/Procedural memory:** Does not require to be consciously recalled (e.g., memory for procedures, skills and habits that are learnt).

C. **Alan Baddeley and Graham Hitch's theory of tripartite working memory has four components:**
   1. ***Central Executive:*** Supervises and controls flow of information to and from the other three components (aka slave systems). It also deals with cognitive tasks such as mental arithmetic and problem solving.
   2. ***Visuo-spatial sketchpad*** **(aka inner eye):** Stores the information in visual or spatial form.
   3. ***Phonological loop:*** Deals with written and spoken material; two types:
      1. **Acoustic/phonological stores:** Deals with speech perception
      2. **Articulatory control process (acoustic loop):** It is used to rehearse and store information from acoustic store.
   4. ***Episodic Buffer:*** It links information across domains to form integrated units of verbal, spatial and visual information with time sequencing (chronological ordering). It is linked to long term memory.

D. **Craik and Lockhart's depth of information processing theory of memory:**
   - ***Shallow processing*** of the appearance/physical form (structured) and sounds (phonemic)
      - Leads to short term retention
   - ***Deep processing*** of meaning of a word and relating it to similar word with similar meaning
      - Involves elaborative rehearsal of information and hence leads better recall

Q. Explain motivation and its theories.

Motivation refers to the driving forces guiding the persistent behavior directed towards particular goal:

- **Drive/Push theory:** ***Internal driving force*** pushes the individual to engage in behavior leading towards the goal aka goal-directed behavior, which in turn reduces the intensity of driving force
- **Incentive theory:** Goals/Incentives acts as ***external pulling forces***
- **Opponent process theory:** Individual is motivated to ***seek*** goals that give emotionally ***good feeling*** and ***avoid*** those that give ***displeasure***
- **Optimum level theories:** Individual is motivated to behave in such a way as to ***maintain*** an ***optimal level of arousal***
- **Maslow's theory of self-actualization:** Behavior motivated by the drive for ***satisfaction of a set of needs arranged in a universal hierarchy to attain self-actualization*** (development of one's full potential as a unique human being)
   - Hierarchy of satisfaction of needs: physiological (hunger, thirst etc.), safety, love and belongingness, esteem (to be competent), cognitive (to understand/explore), aesthetic (symmetry, order, beauty) and self-actualization.

Q. Describe principles of personality development.

Personality consists of the distinctive patterns of behavior (including thoughts and emotions) that characterize each individual's adaptation to the situations of his or her life.

There are seven principles of personality development:

1. **Cumulative Continuity Principle:** Personality traits increase in rank-order consistency as people get older.
2. **Maturity Principle:** People become better equipped to deal with the demands of life as they acquire experience and skills.
3. **Plasticity Principle:** Personality can change at any time (but such change may not be easy).
4. **Role Continuity Principle:** Taking on roles or images can lead personality to be consistent over time.
5. **Identity Development Principle:** People seek to develop a stable sense of who they are, and then strive to act consistently with this self-view.
6. **Social Investment Principle:** Changing social roles at different stages of life, such as becoming a spouse, parent, or boss, can cause personality change.
7. **Corresponsive Principle:** Person-environment transactions can cause personality traits to remain consistent or even magnify over time.

Theories of personality development:

- ***Sigmund Freud's dynamics of personality:*** Human personality is expressed in dealing with conflict between:
    - Impulse (id) and restraint (superego)
    - Aggressive/pleasure seeking biological urges and internalized social controls over these urges
    - Personality arises from individual's efforts to resolve this basic conflict to express these impulses in ways that bring satisfaction without also bringing guilt or punishment (ego)
- ***Sigmund Freud's stages of psychosexual development:***
    - Personality develops as a child passes through a series of psychosexual stages. During each stage, the pleasure-seeking impulses of id, focus on a particular area of body and on activities connected with that area
    - Conflicts unresolved during earlier psychosexual stages could surface as maladaptive behavior in the adult years.

SIGMUND FREUD'S STAGES OF PSYCHOSEXUAL DEVELOPMENT

Stage	*Focus*
Oral (0–18 months)	Pleasure centers on the mouth-sucking, biting, chewing
Anal (18–36 months)	Pleasure focuses on bowel and bladder elimination; coping with demands for control
Phallic (3–6 years)	Genitals are the pleasure zone is the genitals; coping with incestuous sexual feelings
Latency (6 to puberty)	A phase of dormant sexual feelings
Genital (puberty on)	Maturation of sexual interests

- ***Erik Erickson*** described eight stages of ***psychosocial*** personality development. He chose to focus on how social relationships impact personality development extending beyond childhood to look at development across the entire lifespan:

ERIK ERICKSON'S PSYCHOSOCIAL STAGES OF PERSONALITY DEVELOPMENT

Age	*Stages of psychosocial development*	*Virtue*
Birth–18 months	Trust v/s Mistrust	Hope
18 months–3 years	Autonomy v/s Shame and Doubt	Will
3–5 years	Initiative v/s Guilt	Purpose
5–12 years	Industry v/s Inferiority	Competence
13–20 years	Identity v/s Role confusion	Fidelity
21–40 years	Intimacy v/s Isolation	Love
40–60 years	Generativity v/s Stagnation	Care
60 years till death	Integrity v/s Despair	Wisdom

- Lawrence ***Kohlberg's*** stages of ***moral*** personality development focusing on the growth of moral thought:

Kohlberg's stages of moral personality development	
Level 1: Preconventional; values in external events	Stage 1: Acting to avoid punishment
	Stage 2: Acting to further one's own self-interest
Level 2: Conventional; performing right roles	Stage 3: Meeting the expectations of others
	Stage 4: Upholding laws to meet societal expectations
Level 3: Postconventional; shared standards, rights, duties and principles	Stage 5: Personal values used to achieve social consciousness
	Stage 6: Self-selection of universal moral principles

- ***Gordon Allport's trait theories of personality:***
    - He describes trait as a neuropsychic structure having capacity to render stimuli into functionally and meaningfully consistent forms of adaptive and expressive behavior; the three traits described below form the building blocks of individuals personality.

  - **Cardinal traits:** Dominate individual's whole life (i.e., their names are synonymous with these qualities, e.g., Freudian, Gandhian, Nehruvian, Christ)
  - **Central traits:** Describes major characteristics of a person (e.g., intelligent, shy, pious, witty)
  - **Secondary traits:** Related to attitudes or preferences, often appearing only in certain situations/under specific circumstances (e.g. prefers fashionable clothes, loves ice cream).

Q. PS1.1 Establish rapport and empathy with patients.

Discuss Four Models of Doctor-Patient Relationship

	Decision-making responsibility	*Level of disclosure of medical information*
Paternalistic/ autocratic	Doctor	Minimal
Deliberative	Doctor > patient	Selective
Interpretative	Patient > doctor	Major
Informative	Patient	Complete

Important Names in Psychiatry

- **Johann Christian Reil:** Coined the term "Psychiatry", Father of Psychiatry
- **Philippe Pinel:** Unchaining and humane treatment of mentally ill
- **Sigmund Freud:** Father of Psychoanalysis, interpretation of dreams, structure of mind
- **Ugo Cerletti and Bini:** ECT
- **John Cade:** Lithium

Terminologies

- **Rapport:** Meaningful and therapeutic relation between patient and healthcare provider
- **Empathy:** Ability to understand what and how others feel
- **Stigma:** Sign of disgrace that sets a person apart from others
- **Stereotype:** Generalized belief about a particular group/class of people
- **Prejudice:** Affective feeling toward an individual solely based on his group membership

Q. PS1.2 Describe the components of communication.

Components of Communication

- ***AIDET Model:***
  - ***Acknowledge:*** Greet the patient positively and be attentive
  - ***Introduce yourself:*** Name, role and strengths
  - ***Duration:*** Reasonable time should be given to every patient
  - ***Explanation:*** Inform the patient of your observations, clarify their concerns
  - ***Thank:*** Appreciate the patient for their cooperation
- ***RESPECT Model***
  - ***Rapport:*** Develop a meaningful therapeutic communication, avoid assumptions/judgement
  - ***Empathy:*** Understand and acknowledge the patient's perspective of one's behavior/illness
  - ***Support:*** Explore and help overcome barriers to care and compliance
  - ***Partnership:*** Ascertain that physician and patient are a team working together to address medical problems
  - ***Explanations:*** Ask patient to reflect what they understood, clarify the misconceptions if any
  - ***Cultural Competence:*** Professionally address cultural differences between patient and physician
  - ***Trust:*** Allow reasonable time for the patient to trust the physician to allow necessary self-disclosure

Q. PS1.3 Demonstrate breaking of bad news in a simulated environment.

Q. Discuss SPIKES protocol for breaking bad news.

SPIKES protocol is followed for breaking bad news:

- **S**: Setting up and starting the conversation
- **P**: Elicit patient/family members perception
- **I**: Invite them to ask what they would want to know
- **K**: Provide knowledge in small pieces
- **E**: Recognize and empathize with their emotions
- **S**: Set out strategy of plan of action and summarize the gist of the conversation

CHAPTER 21

AETCOM—Attitude, Ethics and Communication Manual

MODULE 4.1: THE FOUNDATIONS OF COMMUNICATION—5

Background

Communication is a fundamental prerequisite of the medical profession and besides skills are crucial in ensuring professional success for doctors. This module continues to provide an emphasis on effective communication skills. During professional year phase III part II (year four), the emphasis is on communicating, diagnosis, prognosis and therapy effectively.

Types of Communication

Q. What is communication? What are the types of communication? Discuss the importance of efficient communication in healthcare settings.

Communication is a process by which information and understanding is exchanged between individuals, by any effective means.

Verbal Communication

- Verbal communication occurs when we engage in speaking with others.
- Can be face-to-face, over the telephone, or online, it is not just about the words, it is also about the caliber and complexity of those words, how we string those words together to create an overarching message, as well as the intonation (pitch, tone, cadence, etc.) used while speaking.

Nonverbal Communication

- Nonverbal communication includes facial expressions, posture, eye contact, hand movements, and touch.
- A person might agree with your idea verbally, but their nonverbal cues: avoiding eye contact, sighing, scrunched up face, etc. indicate something else.

Written Communication

- Whether it is an email, a memo, a report, a social media post, etc.
- Have the same goal to disseminate information in a clear and concise manner—though that objective is often not achieved.

Listening

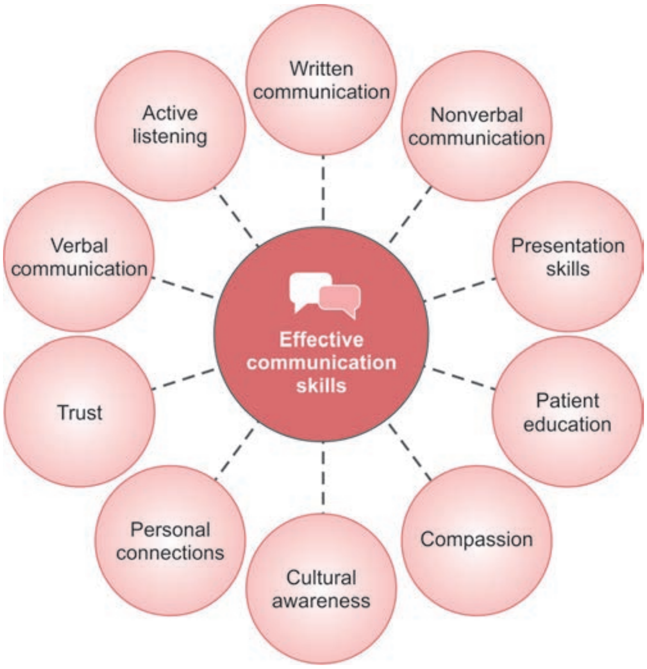
The act of listening does not often make its way onto the list of types of communication. Active listening, however, is perhaps one of the most important types of communication because, if we cannot listen to the person sitting across from us, we cannot effectively engage with them.

Visual Communication

Videos, images, etc., on display or on social media platform, and advertisers use imagery to sell products and ideas.
Importance of efficient communication in healthcare setting:

- A physician's communication and interpersonal skills involve the ability to obtain information to facilitate the precise diagnosis, counsel suitably, give therapeutic instructions, and establish a compassionate relationship with the patients.

- The goal of any communication with the patient is for the physician to learn the patient's experience and facilitate improving their well-being.
- Communication is the foundation for obtaining medical history, as well as conveying a diagnosis and treatment plan.
- Good communication skills by physicians have been shown to improve patient satisfaction, adherence to therapies, and to reduce the likelihood of malpractice claims
- Establishing a trusting relationship with common goals is critical for mutually beneficial physician–patient interactions.



Competencies Addressed

The student should be able to:	*Level*
1. Demonstrate ability to communicate to patients in a patient, respectful, nonthreatening, nonjudgmental and empathetic manner	SH
2. Communicate diagnostic and therapeutic options to patient and family in a simulated environment	SH

Contents

This module includes three interdependent learning sessions:

1. Introductory small group session on the principles of communication with focus on administering communication, of diagnosis, prognosis and therapy.
2. Focused small group session with role play or video where students have an opportunity to observe critique and discuss common mistakes in communicating diagnosis, prognosis and therapy.
3. Skills lab sessions where students can perform tasks on standardized or regular patients with opportunity for self-critique, critique by patient and by facilitator.

Assessment

1. **Formative:** Participation in session 2 and performance in session 3 mentioned above may be used as part of formative assessment.
2. **Summative:** A skills station in which the student may communicate a diagnosis management plan and prognosis to a patient.

Questions

Q. What are the essential elements of physician-patient communication in medical encounters?

Communication and interpersonal skills of a doctor encompass the ability to acquire information to establish a relationship with the patient, to facilitate accurate diagnosis, to provide therapeutic instructions, and to counsel appropriately.

Essential Elements of Communication in Medical Encounters in Accordance with the Kalamazoo Consensus Statement

The essential elements of physician-patient communication include the following:

a. **Open the discussion by:**
   - Allowing patients to complete their opening statement
   - Eliciting the patient's full set of concerns
   - Establishing and maintaining a personal connection

b. **Gather information:**
   - Using open-ended and closed-ended questions appropriately
   - By actively listening using nonverbal (eye contact) and verbal (words of encouragement) techniques

   In order to structure, clarify and summarize information.

c. **Understand the patient's perspective by:**
   - Exploring contextual factors: Age, gender, family, culture, socioeconomic status, spirituality
   - Exploring beliefs, concerns, and expectations about health and illness
   - Acknowledging and responding to the patient's ideas, feelings and values

d. **Share information:**
   - Using language, the patient can understand
   - By checking for patient's understanding
   - By encouraging questions

e. **Reach agreement on problems and plans by:**
   - Encouraging the patient to participate in decisions to the extent they desire
   - Checking the patient's willingness and ability to follow a plan
   - Identifying and enlisting resources and supports

f. **Provide closure by:**
   - Asking if the patient has other issues or concerns
   - Summarizing and affirming agreement with the plan of action
   - Discussing follow-up (next visit, plan for unexpected outcomes)

Q. Discuss common mistakes in communicating diagnosis, prognosis and therapy.

Popa-Velea and Purcărea described two major communication flaws most patients complain about: lack of physician communication skills, and the persistence of an asymmetric therapeutic communicational model. Communication obstacles brought by the disease itself or by several variables pertaining to the patient, including specific demographic and psychological contexts, and the sociocultural context are other barriers in communication.

- **Lack of physician communication skills or their deterioration throughout the disease:** One may have poor communication skills inherently or due to their upbringing and lack of social interactions during the childhood. This may have major impact later in life, both social and professional, affecting the doctor-patient relationship significantly in case of a doctor. Training in medical schools focusing on communication skills and regular practice of talking to patients following the above essential elements of communication will help overcome this issue.
- **The persistence of an asymmetric therapeutic communicational model:** It prevents the initial patient from understanding important facts regarding the causes of disease or function of the medication. This results in poor transmission of information to the patient, communication during daily therapeutic encounters, and ultimately, a patient's opinion of the doctor. Such impressions can have a major impact on the patient's overall psychological state and frequently the prognosis.
- **The particularities of the disease itself:** For instance, in many psychological or psychiatric diseases, doctors must deal with cognitive obstacles (such as the distortion of messages that are exchanged in the therapeutic relationship); in some somatic conditions, symptoms can impair the patient's capacity for explanation, listening, or understanding (e.g., pain, neurologic disorders, etc.).
- **The characteristics of the patient:** Personality type, for instance, oftentimes offers a highly strict or constrained framework for the doctor-patient relationship. Patients with personality disorders frequently are unaware of their shortcomings and put little effort into communicating since they do not anticipate or desire any changes in their way of life. They frequently use projection as a coping method when they don't feel understood or supported, therefore they tend to respond by refusing to follow rules, displaying latent or overt animosity, or transferring unpleasant feelings.
- **Demographic variables:** Such as age (e.g., elderly people are exposed to limited or distorted communication, via cognitive impairments or age-illness stereotype). *Sociocultural context*, which creates a high variability on the way patients express their suffering and on their focus.

MODULE 4.4: CASE STUDIES IN ETHICS EMPATHY AND THE DOCTOR-PATIENT RELATIONSHIP

Background

This module discusses some nuances in the doctor-patient relationship including—failure of therapy, termination of relationships, etc.

Competencies Addressed

The student should be able to:	***Level***
1. Demonstrate empathy in patient encounters	SH
2. Communicate care options to patient and family with a terminal illness in a simulated environment	SH

Case: A Letter from the Grave

Respected doctor,

I am writing this letter with extreme sadness. As you may know that it has been three months since my wife and your patient Mrs. Alka Chaturvedi has passed away. I am writing this letter not with anger or with spite; I am writing this only with the intent that my wife's death not be in vain and that the lessons that can be learned from the way you took care of her may be valuable to other patients in your care and that they will receive the compassion and care from you that Alka never received.

As you may recall, Alka was diagnosed with breast cancer 5 years ago. We rushed to you knowing your reputation as a talented oncologist and we were not disappointed. Your aggressive approach to the disease made all the difference. Surgery and aggressive chemotherapy, while distressing, helped Alka beat the disease and she lived disease-free for 2 years. We were very happy and were and still are very grateful to you. But fate had ordained that our joy will be short-lived. The disease came back with a vengeance. Even at this time you did not give up hope and took on the disease like a warrior but then there came a time that it was clear that the disease had won. We were devastated.

Alka looked up to you as a doctor to provide her with support but it looked like that you were unable to confront the failure. While you did prescribe pain medications and your office helped us find a home nurse you were reluctant to meet Alka or talk to her. When we called for appointments, your office would tell us to contact our family doctor for pain medications. When we did get to see you would not even look at Alka's eyes. You would distractedly talk to her, refill her pain medications and dismiss us quickly. It was as if we were seeing a different doctor than the one we had seen when all was well. And when Alka was admitted to the hospital where she breathed her last you would not even come and see her. We made so many requests for you to come and visit with her. I even called and told you that it would mean so much for her to see you before she departs but you did not.

Would it have been too much for you to come and hold her hand for a minute or say a kind word? Doctor—I am not as learned as you are but patients come to you and repose their faith in you to help them through their illness. We come to you not with the expectation that a cure is always possible but always with the expectation that you will support us in coping with the disease and the tremendous effects it has on our lives. We don't always expect you to succeed but we always expect you to show us care and compassion. I hate to point to out, doctor, that you abandoned Alka when it was clear that she will not be a trophy that you can parade as a success. You abandoned Alka and us at the time we needed you most. You sir, abandoned us when we were most vulnerable.

I write this to you not to fault your knowledge and skills which are considerable. I bear you no ill will. I am grateful that you gave Alka and our family a few more years of togetherness. I am only write to remind you that knowledge and skills are not sufficient for a doctor. Compassion, empathy and nonabandonment are superior virtues. I can only hope that Alka's experience with you will help you take care of your other patients who may not all be successes, as you seem to define it. If only you provided patients empathy, all your patients will be your successes, irrespective of outcome.

Sincerely

Points for Discussion

1. The role of a doctor as a healer.
2. Failure of treatment and its implications for the doctor-patient relationship.
3. Empathy and patient care.
4. Can the doctor-patient relationship be terminated?
5. Hospice care.

Assessment

1. **Formative:** The student may be assessed based on their active participation in the sessions.
2. **Summative:** Short questions on: (1) Empathy, (2) Doctor's responsibilities in the doctor-patient relationship, (3) Doctor's responsibilities in the care of the terminally ill patient.

Questions

What is the Role of a Doctor as a Healer?

Despite the fact that doctors are supposed to develop a wide range of competences during their training and take on a variety of responsibilities in practice, patients and the public still view doctors primarily as clinical healers. In order to conduct a thorough medical examination, the doctor draws on his expertise in medicine, clinical techniques, and experience to identify the patient's issues, expectations, and preferences before formulating a therapy or the therapeutic plan's objectives.

Respect for people is the core professional ethical rule that every doctor must follow. Respecting the wishes of the patients and being concerned for their welfare make up the two components of this ethical concept. Respecting a patient's autonomy promotes recovery by fostering trust. Respect, empathy and sincerity are essential components in the doctor-patient relationship. In the therapeutic role, the doctor has a moral and legal obligation to prioritize the medical welfare and interests of the patient over their own and other parties' interests. This guiding principle of prioritizing the patient's interests is crucial for repairing relationship imbalances as well as for demonstrating the selflessness needed to foster confidence and trust. A patient won't agree to tests or follow instructions until they have grown to trust the doctor. Conflicts of interest arise when a practitioner prioritizes their personal interests or benefit over that of the patient. They introduce prejudice, obstruct wise healthcare decisions, jeopardize clinical results, and also has the potential to erode confidence and trust.

The physician should continue to offer prompt, appropriate care. The doctor has a moral and legal obligation to attend to the patient's requirements as they arise and shouldn't hand off important tasks to junior staff members. In this situation, they must make sure the attending clinician is qualified. The doctor should never abandon the patient, and should continue care until an appropriate transfer is completed. When necessary, they should emphasize the referral's urgency and make such referrals easier. They should give all significant and pertinent information when referring. The doctor should only utilize the patient's information for that patient's benefit. By protecting the confidentiality of all information, even that obtained outside the doctor-patient relationship, the doctor is required to keep this privileged information provided by the patient in confidence. Although violating confidentiality may not result in immediate bodily injury, it seriously undermines confidence and trust and harms the partnership. Physicians must refrain from having inappropriate connections with patients since they are aware of their natural fragility and dependence. Never may a clinician use a patient for financial gain, or other private interests. Inappropriate relationships cannot be defended by informed consent.

Patients require doctors that are knowledgeable, kind, and trustworthy who prioritize their patients' needs for a successful recovery. The therapeutic doctor-patient relationship is a partnership characterized by trust, respect, empathy, and sincerity.

What is the Failure of Treatment and its Implications for the Doctor-Patient Relationship?

Treatment failure is a complex occurring in all parts of healthcare system. Faulty interaction and communication between doctor and patients, and between specialities are the most important factors. Other reasons would be patient noncompliance, nonresponders or disease/organism resistance, doctor's lack of experience, to name a few.

Insufficient information about the disease and about the treatment including the drug dosage, frequency, adverse effects and availability of treatment alternatives is to be discussed in detail with the patient during the initial visit. This will help patient understand what to expect out of the treatment, and enable patient to identify if there is treatment failure allowing patient to return for change in treatment regimen. This becomes true when the patient takes complete responsibility of their treatment. The other reasons why one could observe treatment failure is noncompliance to the treatment. The patient is solely responsible for this. At this point, it is important to involve a family member or a friend in management of the patient's disease, by explaining to them about the regimen and importance of it. Certain patients may not respond to a type of treatment (e.g., due to inherent inability to convert drug into active form). Some diseases may be resistant to certain drugs, like in steroid-resistant nephrotic syndrome for example, or in certain infections caused by the organisms that are resistant to the chemotherapeutic agent(s). Following guidelines and understanding the protocols will help in determining the next line of treatment in these patients. The health service center will take complete responsible for patients who have had severe complaints despite following all recommendations, or when the patient is admitted to the center for an illness or to undergo a procedure. It falls into the hands of the center, through the healthcare workers, to help patients achieve treatment goals. The doctor involved in the treatment of the patient should be competent enough to diagnose and treat appropriately. The doctor may decide to seek a specialist's help when they find it difficult to come to a diagnosis or when patient is not responding to a standard treatment care.

In the therapeutic role, the doctor should prioritize the medical welfare and interests of the patient. A patient may not agree to tests or follow instructions until they have grown to trust the doctor. Treatment failure can have negative impact on the doctor-patient relationship. This relationship starts failing when patient realizes that the treatment advised has met the goals. They may assume the doctor is incompetent and try to seek help from another doctor. This can be avoided by explaining to the patient about the possible reasons of treatment failure and to anticipate them during the first consultation, and if they do fail, what is the next plan of action. In general, failure should be seen as a learning prelude to success. Any treatment failure should be discussed with the colleagues or departmental meetings to help recognise these events and also avoid it in future.

What is Empathy and Patient Care?

Empathy is frequently described as "feeling as others," yet its worth has been disputed. The notion of empathy in the medical field has been contested by academics; some contend that clinical empathy is restricted to a purely cognitive comprehension of emotional states, while others contend that clinical empathy should represent the humane intent of medicine. It appears that objectivity, emotional distance, and detached concern are all inclusive and leave no or insufficient room for the human aspects of illness. It has been demonstrated that this phenomenon has detrimental effects on both patients and healthcare professionals.

Objectivity, detached concern and emotional distance care are hallmarks of mainstream medical culture. The medical profession has become overly focused on science at the expense of the human aspects of disease and multifaceted components. Clinical empathy has been defined as the ability to observe emotions in others, the ability to feel those emotions, and finally the ability to respond to those emotions. The empathic communicative response goes beyond verbal expression. Nonverbal communication includes body language, such as tone of voice, facial emotions, posture, and natural gestures. Clinical empathy includes a thorough cognitive and sensory comprehension of the patient's feelings. As a result, it is neither total immersion in the experience of the other nor emotional detachment.

Patients have expressed a desire for caregivers to be more approachable. It makes an effort to move medicine in the direction of a relationship-centered care model, where the human element is crucial and patients' experiences are valued. In this case, therapeutic empathy is seen as a way to support patients' emotional experience and expression. Clinical empathy benefits people on many different levels by fostering communication, trust, and understanding. Generally speaking, it has been shown that providing empathic care increases autonomy, lowers emotional discomfort, and improves therapeutic outcomes and patient satisfaction of care. Positive clinical outcomes, including patient adherence to the treatment plan and interest in medical advice, are produced through empathic patient care. Empathy has also been found to aid patients' comprehension of available treatments and involvement in therapeutic decision-making.

Can the Doctor-Patient Relationship be Terminated?

It is fair to think about ending the connection, if a practitioner's capacity to manage the patient is insufficient or compromised as a result of an emotional, financial, or legal situation. Taking contemporaneous notes, writing to the patient and their main care physician, establishing continuity of care, and interacting with authorities, if necessary, have all been listed as practical actions that are frequently advised.

Terminating a therapeutic relationship can be particularly challenging and onerous for the treating medical practitioner. A practitioner may want to end the connection for a variety of reasons, from inappropriate behavior and violence to legal action. When ending this, due regard for their professional and legal obligation should be made. Generally, the relationship ceases by mutual agreement for reasons like the patient moving to a new place or no longer needing therapy. The patient might be referred to another doctor who will take over their care. Even though these situations not problematic, they should nonetheless be thoroughly documented.

The patient must be fully informed of the clinician's decision, and preparations must be made to maintain continuity of care, including the dissemination of pertinent clinical information. This point of view seems to have assisted in the identification of a number of practical requirements that must be met in order to successfully end the therapeutic partnership without violating ethical and legal commitments. There must be records of all communications and meetings in the patient's file. Poor health outcome or a patient filing a lawsuit alleging an unreasonable refusal to treat could result from inadequate communication paired with a failure to establish clear boundaries to conclude the relationship amicably.

What is Hospice Care?

Hospice care consists of palliative care provided at the end of life that provides comprehensive comfort care for patients and support for family members. This includes offering the patient the medical care, pain management, and emotional and spiritual support they desire and need. According to the eligibility requirements, a doctor must conclude that the patient's prognosis calls for an anticipated life expectancy of 6 months or less if the illness progresses as expected. When hospice care best satisfies a patient's objectives, family physicians can be important allies in assisting patients and family members with the transition. An interdisciplinary team that includes family doctors, physician medical directors, nurses, social workers, counselors, home health aides, and skilled volunteers provides hospice care.

Although where hospice care is typically administered in patient's house, when symptom control is required, hospice care may also be given in long-term care institutions, hospice facilities, and hospitals. In comparison to normal treatment, hospice care has been linked to improved symptom relief, better fulfilment of patients' end-of-life desires, and higher overall ratings of the quality of end-of-life care. Family doctors are best suited to handle and organize patients' needs for hospice care.

MODULE 4.8: DEALING WITH DEATH

Background

Thanatology is a branch of science that deals with death. Death is an event that any medical student will inevitably face during the course of their professional career. Dealing with death empathetically and at the same time not being overwhelmed by it is an important coping skill for doctors.

Competencies Addressed

The student should be able to:	*Level*
1. Identify conflicts of interest in patient care and professional relationships and describe the correct response to these conflicts.	SH
2. Demonstrate empathy to patient and family with a terminal illness in a simulated environment.	SH

Case: The Empty Bed

You are a house surgeon in the night shift of the ICU. A 19-year-old girl Sharmila is wheeled into the ICU. She has a complicated history. She had surgery for cyanotic congenital heart disease at age 8. She has a history of severe asthma often requiring admission for steroids. She lives in a home near a construction site and recently the attacks have flared up. She now has frequent admissions for asthma exacerbations. She is now constantly on steroids. In the last month, she has had three admissions. But, she fights it bravely. She carries her books with her when she comes in and after the attack settles down she sits quietly reading. Despite the struggle you noticed that the staff nurses liked her. She was positive and charming. Today was no different but the attack seemed worse.

In the ER, the FEV1 was horrible. They had pumped her with steroids, put her on continuous nebulization, an aminophylline infusion was in place when you received her. The smile was smaller but there. The face was cushingoid with all the steroids and the body looked tired. She was moved to her usual bed number 9. Your shift was getting over at 7 AM. but you stayed on an hour. She looked better, the smile was back you reassured her and said I'll be back in the evening and left.

That evening you report for duty and as you look through the patients, bed number 9 is empty. "Have you discharged Sharmila?" you asked the nurse. No doctor—she developed a sudden cardiac arrest at 12 noon—we could not revive her.

Points for Discussion

1. How should doctors deal with the emotions of patients and family facing death?
2. What does the patient experience when he/she is dying? Can physicians make the process of death comfortable?
3. What are the emotions faced by doctors when confronting death in patients? Is death a defeat for the doctor? Should the doctor be emotionally detached from a dying patient?
4. What are the cultural aspects of dying?

Alternate Case: I have Decided to Die

You are a physician in a community care practice for over 20 years and caring for various patients. Mr. Bhaskara Rao is a patient in your care for the past 14 years. He is 76-year-old and has diabetes for the past 30 years. He had renal failure for the past 10 years and is CKD stage V requiring dialysis for 3 years. While he is following up with the nephrologist, he values your position in his family as a family doctor and regularly visits you to check if his treatment is correct and more often to seek reassurance. He has invited you to all his family events—the last being one month ago for his grandson's wedding.

This morning you get a call from him. "Doctor! He says in his usual cheerful voice. Can I meet you tomorrow? I have fulfilled all my responsibilities in life. I am not sad. My children are all settled; my grandson is married; my wife as you know is no more. I have decided to stop my dialysis and say goodbye to this world. I thought I'll talk to you about how to prepare for my death!"

Points for Discussion

1. Can patients choose to die? Is there a role for doctors in the death of patients? Can doctors assist death?
2. How should doctors deal with the emotions of patients and family facing death?
3. What does the patient experience when he/she is dying? Can physicians make the process of death comfortable?
4. What are the emotions faced by doctors when confronting death in patients? Is death a defeat for the doctor? Should the doctor be emotionally detached from a dying patient?
5. What are the cultural aspects of dying?

Assessment

1. **Formative:** Participation in sessions may be used as part of formative assessment. Submitted narrative on the socio-cultural aspects of death may be used as assessment.
2. **Summative:** Short question on assisted dying.

Questions

Can Patients Choose to Die? Is there a Role for Doctors in the Death of Patients? Can Doctors Assist Death?

Before the Mental Healthcare Act, which became effective in 2018, attempted suicide was a crime punishable under Section 309 of the Indian Penal Code. The statute calls on governments to offer mental healthcare and rehabilitation rather than punishment. The idea of the "right to die" is founded on the notion that everyone has the right to end their life or submit to voluntary euthanasia. When a person has this right, it is frequently assumed that they use assisted suicide, or decline life-prolonging treatment if they have a terminal illness or lack the will to live. But this concept of "right to die" is debated for time now.

The doctor assumes the role in assisting a patient during euthanasia. Euthanasia is practice of intentionally ending life to eliminate pain and suffering. It can be passive or active. Passive euthanasia is when patient's life support measures necessary to continue one's life expectancy are withdrawn. Active euthanasia entails use of active lethal substance to end one's life. In India, passive euthanasia was legalized in 2018. The decision was made as part of the judgment in a case concerning Aruna Shanbaug, who passed away in 2015 after being in a persistent vegetative state. The Supreme Court specified two irreversible conditions to permit passive euthanasia: (i) The brain-dead for whom the ventilator can be switched off; (ii) Those in a persistent vegetative state for whom the feed can be tapered out and pain-managing palliatives be added, according to laid-down international specifications.

The following guidelines were laid down regarding passive euthanasia in India:

1. A decision has to be taken to discontinue life support either by the parents or the spouse or other close relatives, or in the absence of any of them, such a decision can be taken even by a person or a body of persons acting as a next friend. It can also be taken by the doctors attending the patient. However, the decision should be taken bona fide in the best interest of the patient.
2. Even if a decision is taken by the near relatives or doctors or next friend to withdraw life support, such a decision requires presence of two witness and countersigned by first class judicial magistrate and should also be approved by a medical board set up by the hospital.

Active euthanasia is illegal in India and in several countries throughout the world.

How Should Doctors Deal with the Emotions of Patients and Family Facing Death?

The five stages of dying by Kubler-Ross are as follows:

1. **Denial** is a protective mechanism used by patients who initially deny the truth of a fatal prognosis. It's critical to communicate facts clearly and give them time to comprehend the news.
2. **Anger:** Patients may vent their wrath at their doctors, their families, or even spiritual beings. Recognizing anger as a normal emotion enables loved ones and medical professionals to react with sensitivity.
3. **Bargaining:** Which may be reasonable or based on magical thinking, is a means through which patients attempt to acquire some control over their sickness. Caretakers should exercise caution to avoid misleading patients or engaging in excessive patient bargaining.
4. **Depression:** Patients with depression report feeling down, worn out, and uninterested. Caretakers must practice compassion again while acknowledging that these behaviors are a normal part of the grieving process.
5. **Acceptance:** Patients accept the reality of their condition and concentrate on having fun in the time they have left. Making peace with their situation and future planning take precedence. Empathy and support should be given at every level of the process because acceptance may not always be healthier than other phases.

What Does the Patient Experience When He/She is Dying? Can Physicians Make the Process of Death Comfortable?

Dying experiences vary for individuals. Some find it peaceful, with periods of recognition and consciousness followed by lapses. Changes in color, circulation, and breathing start occurring. Gradually, the person will enter complete unconsciousness while still potentially able to hear and sense their surroundings. Restlessness may accompany the dying process for some individuals, but such symptoms can typically be managed with palliative care. During these stages, the palliative care team will provide increased support. Being present for a dying person can make a significant difference. Sitting with them, holding their hand, or speaking calmly and reassuringly can bring great comfort. These seemingly simple acts should not be underestimated, even if the person does not respond.

For everyone involved, the change from treatment to end-of-life care presents difficulties. Healthcare professionals could believe that their job is done and stop attending to the patient, causing them and their loved ones to feel abandoned. When death is near, patients and their families frequently seek advice on the psychological and physiological changes that take place. It is possible for caregivers to provide support and direction during this process by being aware of the stages of mourning. Patients and family need clear explanations from medical professionals to understand terminal disease and deal with considerable loss. To encourage healing and resilience, healthcare professionals also need to be able to manage their own grief.

What are the Emotions Faced by Doctors When Confronting Death in Patients? Is Death a Defeat for the Doctor? Should the Doctor be Emotionally Detached from a Dying Patient?

The loss of a patient they were familiar with or the circumstances surrounding the death may have an impact on doctors. They might be experiencing related sentiments of insecurity, helplessness, shame, or failure, or they might be fearful of criticism as a result of their engagement in the patient's treatment. Inattentiveness, impatience, irritability, mental exhaustion, and burnout are the results of the unrecognized grief. Doctors' ability to deliver high-quality care will suffer as a result of the professional taboo surrounding grief.

A sudden death produces a feeling of shock-and self-doubt. A doctor who is affected by a patient's death may find it difficult to cope when subject to an investigation by their employer or the Medical Council and find this particularly worrying as it may attract further scrutiny and criticism. The doctor may be required to attend an inquest as a witness or to prepare a report for a significant event inquiry or the coroner. The family could file a complaint or file a lawsuit. The mere prospect of these occurrences will make the doctor anxious and stressed.

For doctors who deal with death on a regular basis, they should understand that death is an inevitable aspect of life. But on occasion, it can have a bad impact on a doctor's mental health. As a result, doctors should never feel ashamed to ask for assistance when they need it or to use the available counselling services. Any doctor can be surprised by how a death affects them sometimes, and they should be aware that it is acceptable to feel this way.

No matter the circumstances, dealing with death is frequently painful, and doctors learn coping mechanisms throughout their careers. It may be helpful to be able to compartmentalize sadness over a patient's passing from other elements of life and work. This will help cope with the event better.

What are the Cultural Aspects of Dying?

Although death is a universal experience, grieving habits are very much influenced by culture. All cultures have established polite means of coping with death because it is a common occurrence in life, and tampering with these customs can make it difficult for people to deal while they are grieving. It is crucial for healthcare professionals to understand certain fundamentals about how various cultures may approach and deal with death, even while it is unrealistic to expect them to be familiar with each family's specific grieving rituals and traditions. There are important topics that, despite being challenging, must be covered in interactions between doctors, nurses, and families.

It seems logical that delivering culturally sensitive grief and end-of-life care causes discomfort for healthcare practitioners. The difficulties of being professionally suitable and sympathetic are undoubtedly made more difficult by linguistic and cultural obstacles. Despite the fact that patients and families may want sympathy, counsel, and direction from doctors and nurses, the realities of a scenario frequently entail a rush for time and both physical and emotional tiredness among caregivers and families. Sometimes, when important judgments need to be taken, we just don't show enough warmth and sensitivity in the moment. For individuals with training in the Western Medical Tradition, the clinical facts call for rapid and rational reasoning. Such a straight approach could appear harsh to people from many cultures, and decisions about things like organ donation might be seen as cruel right away after someone passes away. In some cultures, mourners are expected to express their sorrow, including wailing, because the more anguish is shown and the more people grieve, the more the deceased was loved. Other cultures expect moderation. If a doctor breaks news about a terminal illness to a patient directly, family members may react badly in many cultures. Patients and families may respect the right to privacy highly. Carteret suggests asking the following questions to deal with the cultural aspects of death appropriately:

- What are the cultural rituals for coping with dying, the deceased person's body, the final arrangements for the body and honoring the death?
- What are the family's beliefs about what happens after death?
- What does the family consider to be the roles of each family member in handling the death?
- Who should the doctor talk to about test results or diagnosis?

Because patients and families should be considered a source of information about their unique/cultural requirements and conventions, this list of questions is crucial, as healthcare providers are at a loss for what to ask in such tough situations. The level of acculturation is crucial in defining the traditions and beliefs that a family will adhere to as they deal with imminent death, funeral arrangements, and grief.

CHAPTER 22

Immunology

INTRODUCTION

Immune system is defined as the body's defense system that protects against pathogenic microorganisms and noninfectious foreign substances.

Immune system is the third line of defense against infection **(Fig. 22.1)**. Innate and adaptive are the two types of immune response.

DUALITY OF IMMUNE SYSTEM

Humoral (Antibody-mediated) Immunity

- It involves production of antibodies against foreign antigens, by a subset of lymphocytes called B-cells. These B cells are stimulated to form plasma cells and they secrete antibodies.
- Humoral immunity is involved in defense against bacteria, bacterial toxins, and viruses that circulate freely in body fluids, before they enter cells. They are also responsible for certain reactions against transplanted tissue.

Cell-mediated Immunity

Q. Write short note on cell-mediated immunity.

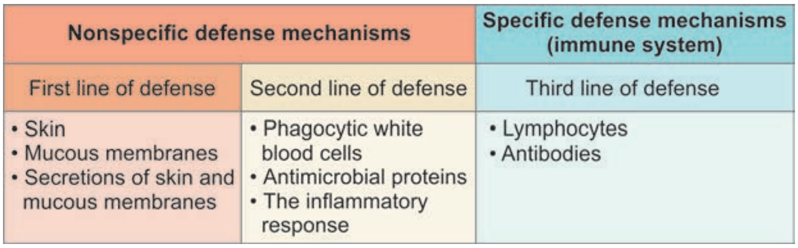
- It involves specialized set of lymphocytes called T-cells that recognize foreign antigens on the surface of cells, organisms, or tissues: Helper T-cells and cytotoxic T-cells.
- Defense against:
    - Bacteria and viruses which lie inside the host cells and are not accessible to antibodies.
    - Fungi, protozoa, and helminths, cancer cells, transplanted tissue.

Antigens

Most of the antigens are proteins or large polysaccharides from a foreign microbes or nonmicrobes:

- **Microbes:** The antigens may be capsules, cell walls, toxins, viral capsids, flagella, etc.
- **Nonmicrobes:** These antigens include pollen, egg white, serum proteins, and surface molecules of red blood cell and transplanted tissue.

Lipids and nucleic acids become antigen only when combined with proteins or polysaccharides.



Nonspecific defense mechanisms		Specific defense mechanisms (immune system)
First line of defense	Second line of defense	Third line of defense
• Skin • Mucous membranes • Secretions of skin and mucous membranes	• Phagocytic white blood cells • Antimicrobial proteins • The inflammatory response	• Lymphocytes • Antibodies

FIG. 22.1: Nonspecific and specific defense mechanisms.

Haptens

These are small foreign molecules which are not antigenic by themselves. They become antigenic when coupled to a carrier molecule. Once antibodies are formed, they will recognize haptens.

Epitope

Epitope represents a small part of an antigen that interacts with an antibody. Each antigen may have one to several epitopes. Each epitope is recognized by a different antibody.

Antibodies

Q. Briefly discuss immunoglobulins and its functions.

- Antibodies (immunoglobulins) are proteins which recognize and bind to a particular antigen with very high specificity.
- These are produced in response to exposure to the antigen.
- One virus or microbe may have several antigenic determinant sites. Each site may bind to different antibodies.
- Each antibody possess at least two identical sites which bind to an antigen. These sites are called antigen-binding sites.
- Valence of an antibody: It is the number of antigen-binding sites in antibody and most antibodies are bivalent.

Antibody structure

- **Monomer:** It is an antibody molecule having a flexible Y-shape with four protein chains, i.e., two identical light chains and two identical heavy chains.
- **Variable regions:** These are two sections at the end of the Y's arms. They contain the antigen-binding sites (F_{ab}). They are identical on the same antibody but vary from one antibody to another.
- **Constant regions:** They represent the stem of monomer and lower parts of Y arms.
    - **F_c regions:** They are regions on the stem of monomer and are important because they can bind to complement or cells.
    - **F_{ab} region:** For antigen binding.

Immunoglobulin classes (Table 22.1)

Functions of immunoglobulins/antibodies

- **Act as opsonins:** Immunoglobulins coat bacterial surface and act as opsonins. This facilitates phagocytosis by cells possessing F_c receptors (e.g., neutrophils).
- **Antibody-dependent cell-mediated cytotoxicity (ADCC):** In this, antibodies bind to microbes via their F_{ab} region. Cytotoxic NK cells attach via F_c receptors and kill these organisms by release of toxic substances called perforins.
- **Activation of complement system:** Binding of antibodies to antigen can trigger activation of the classical complement pathway. Complement components can function as opsonins (C3b component), aid in phagocytosis, chemotaxis (recruitment of leukocytes by C3a and C5a), and cause death of microbes (by MAC-membrane attack complex C5-9).
- **Neutralization:** Some antibodies may directly neutralize the biological activity of their antigen target or toxins released by bacteria. This is an important feature of IgA antibodies at mucosal surfaces.
- **Processing of antigen:** Antibodies present on B lymphocytes help in internalization of antigen and further processing it for presentation to other cells.

TABLE 22.1: Features of immunoglobulin classes.

Features	*IgG*	*IgM*	*IgA*	*IgD*	*IgE*
Structure	Monomer	Pentamer, hexamer	Dimer	Monomer	Monomer
Subtypes	G1, G2, G3, G4	Other chains: J chain	Al, A2		
Percentage serum antibodies	75–85% (IgG1 = 45–53%, IgG2 = 11–15%)	5–10%	7–15%, (IgA1 = 11–14%, IgA2 = 1– 4%)	0.04%	0.003%
Location	Blood, lymph, intestine	Blood, lymph, B cell surface (monomer)	Secretions (tears, saliva, intestine, milk), blood, and lymph	B-cell surface, blood, and lymph	Bound to mast cells and basophils throughout body
Half-life in serum	23 days	5 days	6 days	3 days	2.5 days
Complement fixation	Yes (classical, alternate)	Yes (classical)	No	Alternate pathway	No
Placental transfer	Yes	No	No	No	No
Known functions	Enhances phagocytosis, neutralizes toxins and viruses, protects fetus and newborn	First antibodies produced during an infection. Effective against microbes and agglutinating antigens	Localized protection of mucosal surfaces. Provides immunity to infant digestive tract	In serum function is unknown. On B-cell surface, initiate immune response. Marker of mature B-cell	Allergic reactions and antiparasitic action

- **Agglutination:** IgM antibodies help in agglutination of particulate matter including bacteria and viruses.
- **Immobilization of microbes:** Antibodies against bacterial cilia or flagella may immobilize their movement and ability to escape the phagocytosis.
- **Protection of mucosal surface:** This is observed with IgA type of antibodies.
- **Immune-complex formation:** Antibodies combine with antigen to form immune complexes. The size of these immune complexes varies depending upon the ratio between antigens and antibodies. Larger immune complexes can be removed by the phagocytic cells in the reticuloendothelial (RE) system.
- **Transplacental passage:** Maternal antibodies can pass through placenta from mother to fetus conferring immunity to the fetus.

CYTOKINES

Q. Write short note on cytokines.

The immune response involves multiple interactions between many cells. These cells are lymphocytes, dendritic cells, macrophages, other inflammatory cells (e.g., neutrophils), and endothelial cells. Few of these interactions are due to cell-to-cell contact. However, many interactions and effector functions of leukocytes are mediated by short-acting soluble proteins: multipurpose chemical messengers called **cytokines.** Cytokines which mediate communications between leukocytes are called **interleukins.**

Mode of Action

Cytokines exert their effect by binding to specific receptors on target cells. They may act by three ways:

1. Autocrine when the cytokines act on the same cells which secrete them.
2. Paracrine when cytokines are produced by one cell type which act on adjacent/nearby target cells.
3. Endocrine when the cytokines secreted into the circulation act on target cells at a site distant from their site of synthesis.

Interleukins

- They are produced by and signal between white cells which mediate endocrine communication at a site distant from their site of synthesis.
- **Source:** Activated macrophages.
- **Effects:** Fever, bone marrow release of neutrophils into circulation (leukocytosis), B-cell proliferation, antibody production, and production of IL-2 by T-cells. Interleukin-2 (IL-2) stimulates the proliferation of activated B-cells, T-cells, and NK cells.

Tumor Necrosis Factor-α

- **Source:** TNF-α is produced by activated macrophages in response to infection by bacteria and other microbes.
- **Effects:** Fever, cachexia (pathologic state characterized by weight loss and anorexia seen in neoplastic diseases and some chronic infections), anorexia, shock, enhanced leukocyte cytotoxicity, enhanced NK-cell function, acute phase protein synthesis, proinflammatory cytokine induction, increases apoptosis, and expression of cytokines and adhesion molecules.
- Important cytokines and their functions are given below:

Cytokines	*Family*	*Main source*	*Functions*
IL-1β	IL-1	Macrophages, monocytes	Pro-inflammation, proliferation, apoptosis, differentiation
IL-4	IL-4	T_H-cells	Anti-inflammation, T-cell and B-cell proliferation, B-cell differentiation
IL-6	IL-6	Macrophages, T-cells, adipocytes	Pro-inflammation, differentiation, cytokine production
IL-8	CXC	Macrophages, epithelial cells, endothelial cells	Pro-inflammation, chemotaxis, angiogenesis
IL-10	IL-10	Macrophages, T-cells, B-cells	Anti-inflammation, inhibition of the pro-inflammatory cytokines
IL-12	IL-12	Dendritic cells, macrophages, neutrophils	Pro-inflammation, cells differentiation, induces acute phase proteins
IL-11	IL-6	Fibroblasts, neurons, epithelial cells	Anti-inflammation, differentiation, induces acute phase proteins
TNF-α	TNF	Macrophages, NK cells, CD4$^+$ lymphocytes, adipocyte	Pro-inflammation, cytokines production, cell proliferation apoptosis, anti-infection
IFN-γ	INF	T-cells, NK cells	Pro-inflammation, innate, adaptive immunity, antiviral activity
GM-CSF	IL-4	T-cells, macrophages, fibroblasts	Pro-inflammation, macrophage activation, increases neutrophil and monocyte function
TGF-β	TGF	Macrophages, T-cells	Anti-inflammation, inhibition of pro-inflammatory cytokine production

Interferons

Q. Write short note on interferons.

- They are critical cytokines that play a key role in defense against viral infections and other intracellular microbes (e.g.,*Toxoplasma gondii).*
- This group includes interferon-alpha (IFN-α), interferon-beta (IFN-β), and interferon-gamma (IFN-γ).
- **Sources:**
  - These are produced by a wide range of cells, when attacked by viruses and other non-self-pathogenic antigens.
  - IFN-γ is released by T cells and NK cells.

Erythrocyte Sedimentation Rate

Q. Write short note on erythrocyte sedimentation rate (ESR).

- It is the rate at which red blood cells (RBCs) settle down when anticoagulated whole blood is allowed to stand.
- RBCs have net negative charge on their surface and do not aggregate but tend to repel each other. Plasma proteins have positive charge and neutralize the surface negative charge called Zeta potential of red cells.

Factors Affecting ESR

Plasma factors: Increase in certain plasma proteins (especially fibrinogen), reduces the repulsive forces between the red blood cells and cause them to stack together like tyres, or rouleaux. Rouleaux have more mass/surface area ratio than single red cells, and therefore sediment faster and increase the ESR.

- An accelerated ESR is favored by elevated levels of fibrinogen, globulins, and cholesterol (which increase the positive charge of plasma) whereas albumin and lecithin retard ESR.
- Elevated fibrinogen and raised ESR are also observed in pregnancy, old age, and end-stage renal disease.
- In acute inflammation ESR and acute phase reactants are raised.
- ESR is increased in conditions associated with monoclonal (multiple myeloma) or polyclonal (chronic infections like tuberculosis) increase in immunoglobulins. In systemic lupus erythematosus (SLE), ESR is raised but CRP may be normal.

Red cell factors: The sedimentation rate is directly proportional to the weight of the cell aggregates and inversely proportional to the surface area. ESR may be low if plasma proteins are low or red cell morphology is abnormal making rouleaux formation impossible.

- Anemia increases the ESR and polycythemia decreases it.
- Microcytes sedimentation is slower than macrocytes.
- Red cells with an abnormal or irregular shape, such as sickle cells or spherocytes, do not exhibit rouleaux formation and have low ESR.

Normal range: For men 1–10 mm 1st hour and for women 5–20 mm 1st hour.

Acute Phase Reactants/Proteins (Fig. 22.2)

Q. Write short note on acute phase reactants.

Acute phase proteins are produced by liver in response to inflammatory stimuli.

- **ESR** (discussed above)
- **C-reactive protein:** C-reactive protein (CRP) plays an important role in host defense and stimulates repair and regeneration. CRP is an acute phase reactant produced in the liver.
  - It opsonizes invading pathogens.
  - CRP increases (may be up to 1,000-fold) within 6 hours of acute inflammation. Levels fall within a few days after the inflammation subsides. Sequential measurement of CRP is useful in monitoring disease activity.
  - In some inflammatory diseases there may be normal or slight elevations of CRP concentration despite unequivocal evidence of active inflammation. These include SLE, systemic sclerosis, ulcerative colitis, and leukemia. However, existing infection in these conditions is associated with significantly raised levels of CRP.
  - It is to be noted that intercurrent infection does not cause a significant CRP response in these conditions.

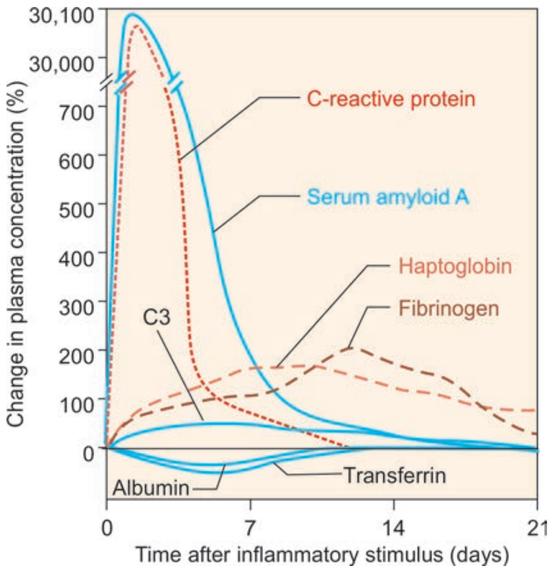


FIG. 22.2: Various acute phase reactants and their levels in inflammation.

- **Procalcitonin** is a 14.5 kDa peptide, a sensitive marker of bacterial infections. It can guide regarding the progression of infections, especially for pneumonia and sepsis. Levels of procalcitonin can be used to guide antibiotic therapy.
- **Ferritin:** During malignancy and infection, ferritin concentrations are elevated. Organisms like pseudomonas cause ferritin levels to drop because they have virulence factor siderophores (pyoverdine and pyocyanin) that chelate and import iron.
- **Haptoglobin:** It is a scavenger protein that has antioxidant, antimicrobial, and anti-inflammatory properties. The levels of haptoglobin decrease during intravascular hemolysis and its levels increase during inflammation.
- **Serum amyloid A** plays a role in host defense and stimulates repair and regeneration. In chronic inflammation, it may contribute to the development of amyloidosis.
- **Fibrinogen** plays an essential role in wound healing.
- **α_1-antitrypsin and α_1-antichymotrypsin:** They control inflammation by neutralizing the enzymes produced by activated neutrophils and prevent tissue destruction.
- **Hepcidin** increases during inflammation causing anemia of chronic disease.
- **Albumin:** Albumin is a negative APP, and its production is decreased to conserve amino acids for positive APPs.
- **Transferrin**: Transferrin is a negative APP. Macrophages internalize transferrin to sequester iron and inhibit microbial iron scavenging.
- **Others:** Ceruloplasmin, alpha-2-macroglobulin, alpha-1-antichymotrypsins, and manganese superoxide dismutase.

COMPLEMENT SYSTEM

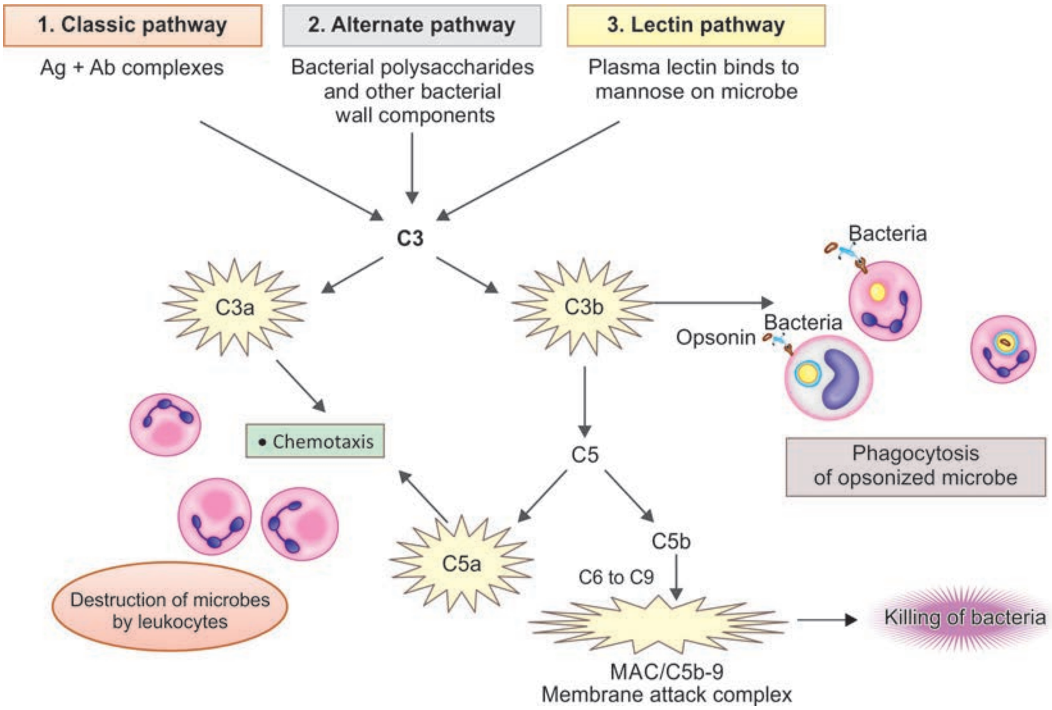
Q. Write short note on the complement system.

- The complement system is a group of plasma proteins (Ω globulins), major source being the liver. C1q produced mainly by bone marrow derived cells like macrophages and dendritic cells.
- They are proteases and are important in both inflammation and immunity.

Pathways of Complement System Activation (Fig. 22.3)

The decisive step in complement activation is the proteolysis of the third component, C3. Cleavage of C3 can occur by any one of three pathways:

1. **Classical pathway:** It is activated by **antigen-antibody** (Ag-Ab) complexes in which C1 binds to antibody (IgM or IgG), acute phase proteins, charged molecules, and apoptotic or necrotic cell debris.



1. Classic pathway
Ag + Ab complexes
2. Alternate pathway
Bacterial polysaccharides and other bacterial wall components
3. Lectin pathway
Plasma lectin binds to mannose on microbe
C3
C3a
C3b
Bacteria
Opsonin
Bacteria
• Chemotaxis
C5
Phagocytosis of opsonized microbe
C5a
C5b
C6 to C9
Destruction of microbes by leukocytes
Killing of bacteria
MAC/C5b-9
Membrane attack complex

FIG. 22.3: Different pathways of activation and functions of the complement system. All pathways of activation lead to cleavage of C3.

2. **Alternative pathway:** This pathway is antibody-independent.
   - It is activated by binding of C3 directly to microbial surface molecules [e.g., endotoxin, or lipopolysaccharides (LPS)], complex polysaccharides, cobra venom, and "altered self" such as tumor cells, **in the absence of antibody.** They **cleave C3 to C3b.**
   - **C3b** in the presence of **factors B and D generates C3bBb** (alternative pathway C3 convertase).
   - **C3bBb is labile** and **degraded by factors I** and H, but **stabilized by properdin** and can subsequently activate C3.
   - This results in persistent and prolonged C3 activation and hypocomplementemia. In addition, decreased synthesis of C3 by the liver is also responsible for hypocomplementemia.
3. **Lectin pathway:** It directly activates C1 when plasma mannose-binding lectin (MBL) binds to mannose on microbes.

Complement System and Disease (Table 22.2)

TABLE 22.2: Genetic deficiencies of plasma complement components and associated clinical findings.

Deficiency	*Infection*	*Autoimmune disease*
Classical pathway		
C1q	Pneumococcal B/M, other pyogenic	SLE, GN, DV/DLE
Clrs	Other pyogenic pneumococcal B/M, DGI	SLE GN
C4	Other pyogenic	SLE, GN, other AD
C2	Other pyogenic, pneumococcal B/M, meningococcal M	SLE, GN, DV/DLE, other AD
C3	Other pyogenic Pneumococcal B/M, meningococcal M	GN, DV/DLE, SLE, other AD
C5, C6, C7, C8, C9	Meningococcal M, DGI, other pyogenic	SLE, GN, other AD
Lectin pathway		
MBL	Other pyogenic, fungal, HIV	SLE
MASP-2	Pneumococcal pneumonia	SLE
Alternative pathway		
Factor D	DGI, meningococcal M, other pyogenic	
Control proteins		
C1 INH	Hereditary angioedema	SLE
Factor I	Other pyogenic, meningococcal M, pneumococcal B/M	
Factor H	Meningococcal B/M, other pyogenic	GN, HUS, SLE
Properdin	Meningococcal M, pneumococcal B/M, other pyogenic	DV/DLE
C4-binding protein		Other AD

(B/M: Bacteremia or meningitis; DGI: Disseminated gonococcal infection; DV/DLE: Dermal vasculitis or typical/discoid lupus erythematosus; GN: Glomerulonephritis in various forms, often membranoproliferative; HIV: Human immunodeficiency virus; HUS: Hemolytic-uremic syndrome; M: Meningitis; MASP: MBL-associated serine protease; MBL: Mannose-binding lectin; other AD: Autoimmune disease (almost all possible diagnoses have been reported); Other Pyogenic: Serious deep or systemic infection due to, or typically caused by, a pyogenic bacterium (abscess, osteomyelitis, pneumonia, bacteremia other than pneumococcal, meningitis other than meningococcal or pneumococcal, cellulitis, myopericarditis, and peritonitis); SLE: Typical systemic lupus erythematosus or an SLE-like syndrome without characteristic serologic findings)

Major Histocompatibility Complex

Q. Write short note on HLA system/major histocompatibility complex (MHC).

All human cells express a series of molecules on their surfaces that are recognized by other individuals as foreign antigens. It was found that major histocompatibility antigens are the important antigens involved in the rejection of transplanted organs. These antigens are encoded by a segment of **chromosome 6 (6p21.3)** known as the major histocompatibility complex.

Significance of MHC/HLA System

Q. List diseases associated with HLA-B27.

- **In transplantation:** HLA typing is prerequisite in selecting appropriate donor and recipient combinations for transplantation.
- **Regulations of cell-to-cell interaction:** During immune response (immune response genes).
- Defense against viral infections.
- **HLA and disease association (Table 22.3):** HLA alleles confer a state of susceptibility, or risk, for disease. Many diseases are known to be associated with certain HLA alleles. The diseases associated with the HLA locus can be broadly categorized as mentioned in **Table 22.3.**

TABLE 22.3: Diseases showing positive HLA antigen association.

System	***Disease***	***HLA antigen***	***Relative risk***
Rheumatologic	Ankylosing spondylitis	B27	90.0
	Reiter syndrome	B27	37.0
	Acute anterior uveitis	B27	8.2
	Reactive arthritis	B27	18.0
	Psoriatic arthritis	B27 B38	10.7 9.1

IMMUNODEFICIENCY

Immunodeficiency may be primary or secondary.

Q. MI1.10 Describe the immunological mechanisms in immunological disorder (immunodeficiency states) and discuss the laboratory methods used in detection.

Primary Immunodeficiency Diseases (Box 22.1)

Classification of Primary Immunodeficiency Diseases

Q. Classify primary immunodeficiency disorders.

Primary immunodeficiency diseases (PIDs) are classified into eight major categories according to the component of the immune system primarily involved **(Box 22.1)**. Common components, their frequency, and their susceptibility in primary immunodeficiency are presented in **Table 22.4.**

Box 22.1: Classification of primary immunodeficiency diseases.

- Combined T-cell and B-cell immunodeficiencies
- Predominantly antibody deficiencies
- Other well-defined immunodeficiency syndromes
- Diseases of immune dysregulation
- Congenital defects of phagocyte number and function
- Defects in innate immunity
- Autoinflammatory disorders
- Complement deficiencies

TABLE 22.4: Common components, their frequency, and their susceptibility in primary immunodeficiency.

Class (Deficiency)	*Relative frequency*	*Susceptibility*	*Treatment*
B lymphocytes	50%	Bacterial infections	Immunoglobulin injection
Combined B and T lymphocytes	10-20%	Viral, bacterial, fungal, and protozoal	Bone marrow transplant
Phagocytes	18%	Bacterial infections	Antibiotics and cytokines
Complement	2%	Bacterial infections and autoimmunity	Infusion of complement components

Warning Signs for Suspicion of Primary Immunodeficiency Disorders (Table 22.5)

TABLE 22.5: Warning signs for suspicion of primary immunodeficiency disorders (PID).

Four or more new ear infections within 1 year	Recurrent, deep skin or organ abscesses
Two or more serious sinus infections within 1 year	Persistent thrush in mouth or fungal infection on skin
Two or more months on antibiotics with little effect	Need for intravenous antibiotics to clear infections
Two or more pneumonias within 1 year	Two or more deep-seated infections including septicemia
Failure of an infant to gain weight or grow normally	A family history of PID

Antibody Deficiencies

Q. Write short note on B-cell (antibody) immunodeficiency disorders.

- Constitute 70% of PIDs.
- Recurrent pyogenic infections starting after 6–12 months. Main types of antibody deficiencies are listed in **Box 22.2.**

X-linked agammaglobulinemia (XLA) (Bruton agammaglobulinemia)

Q. Write short note on XLA.

- Described as the “prototypical antibody deficiency” and is the first immunodeficiency described.
- **Bruton tyrosine kinase** *(Btk)* is necessary for the growth and the maturation of B-cell precursors. It is deficient in this disease.
- **Xq21.3–22** (>300 mutations).
- **B-lymphocytes are decreased,** <1% CD19 or CD20-positive lymphocytes.
- Tonsils are small, no palpable lymph node.

Box 22.2: Main types of antibody deficiencies.

- X-linked and autosomal recessive agammaglobulinemia
- Common variable immunodeficiency
- IgA deficiency
- IgG subclass deficiency
- Transient hypogammaglobulinemia of infancy
- Selective antibody deficiency
- Associated to other immunodeficiencies (Job syndrome, hyper-IgM)

- **Autosomal recessive transmission** due to mutation in the genes of the surface bound μ heavy chain, λ5, and Igα.

Clinical Features: Little Boys With Big Infections!

- Symptoms appear at 6–9 months of age (after loss of maternal Ig).
- **Sites of infection:** Mucous membranes, ear (otitis media), lungs (bronchitis/pneumonia), blood (sepsis), gut (giardia, or enterovirus), skin, eyes, and meningitis.
- Typical bacterial infections include *Haemophilus influenzae* and *Streptococcus pneumoniae.*
- Also seen: Neutropenia, malignancy in older patients, and renal and joint involvements.

Prevention of infections in patients with PID involves avoidance measures, vaccination, prophylactic antibiotics, immune globulin therapy.

Common Variable Immunodeficiency (CVID)

Q. Write short note on common variable immunodeficiency.

- Diagnosis depends on the exclusion of other causes of antibody deficiencies.
- Incidence: 1/10,000–1/50,000 (second or third decade)
- Decrease in IgG, A +/–M. B-cells are normal or decreased.

Clinical Features

- CVID has a tendency to autoantibody formation.
- Chronic pulmonary infections, chronic giardiasis, intestinal malabsorption, atrophic gastritis, and pernicious anemia.
- T-cell immunity may be deficient.
- Increased risk of lymphoreticular and gastrointestinal malignancies.

Box 22.3: Associated conditions with IgA deficiency.

- Common variable immunodeficiency (CVID)
- Deficiency of IgG2 (IgG4, E) and poor response to polysaccharide antigens
- Ataxia-telangiectasia
- Risk of asthma and autoimmune diseases (RA, vitiligo, thyroiditis)
- Auto and allo anti-IgA antibodies (MG!).

IgA deficiency

- Incidence: 1/700 Caucasians but symptoms in <33%.
- Presents with recurrent respiratory infections and chronic diarrhea. Associated conditions with IgA deficiency are listed in **Box 22.3.**

IgG subclass deficiencies

- Normal total serum IgG levels with subnormal levels of one or more IgG subclasses.
- Mutations in heavy chain genes on 14q32.3 (γ1, 2, 3, 4).
- IgG1: Lead to a decrease in total serum IgG.
- IgG2: Most common IgG subclass deficient in children. Frequently associated with poor response to polysaccharide antigens and IgA deficiency.
- IgG3: Most common IgG subclass deficient in adults.
- IgG4: Levels vary widely in normal people.

Transient hypogammaglobulinemia of infancy

- Decrease of the maternal IgG transferred to the fetus during pregnancy but delayed Ig production (IgM, IgG, and IgA).
- Normal range after 36 months.
- Normal response to vaccination.

Selective antibody deficiencies

- Normal total serum levels of IgG and IgM but failure to respond to certain antigens (polysaccharide antigens).
- Asymptomatic or recurrent sinopulmonary infections.
- Found in sickle cell anemia, asplenia, Wiskott-Aldrich syndrome, and DiGeorge syndrome.

Hyper-IgM syndrome

- Deficit in IgM: IgG switch. Elevated IgM levels and a deficiency in IgG, IgA and IgE.
- The most frequent deficit concerns CD154 on CD4+ T-cell (Xq26.3–27.1).

The hyper-IgE syndrome (Job syndrome)

- Recurrent abscesses, eczema, dysmorphy, eosinophilia, and high serum levels of IgE.
- Autosomal dominant and sporadic cases.

Cell-mediated (T-cell) Immunodeficiency (Box 22.4)

Q. Write short note on T-cell (cell-mediated) immunodeficiency disorders.

Box 22.4: T-cell (cell-mediated) immunodeficiency disorders.

- DiGeorge syndrome
- Defect in CD3/TCR
- Defect in signaling
- Defect in cytokine production as IL-2 and IFN gamma
- Defect in cytokine response

Box 22.5: Combined immunodeficiency disorders.

- Severe combined immunodeficiency (SCID)
- Omenn syndrome
- Adenosine deaminase (ADA) deficiency
- Ataxia-telangiectasia (AT) syndrome
- Wiskott-Aldrich syndrome (WAS)
- EBV-associated immunodeficiency (Duncan's syndrome)

Combined Immunodeficiencies (Box 22.5)

Severe combined immunodeficiency (SCID)

Q. Write short note on severe combined immunodeficiency.

- Failure to thrive.
- Onset of infections in the neonatal period.
- Opportunistic infections, chronic or recurrent thrush, chronic rashes, and chronic or recurrent diarrhea.
- Lack of lymphoid tissue including thymus, tonsils, and lymph nodes.
- Characteristic abnormality in adenosine deaminase deficient SCID includes cupping at the end of the ribs demonstrated on a chest radiograph and an absent thymic shadow.
- Common: *Pneumocystis jirovecii* infection, or persistent oral or diaper candidiasis.

Adenosine deaminase (ADA) deficiency, SCID

Profound lymphopenia ($<500/\text{mm}^3$); skeletal abnormalities, including chondro-osseous dysplasia (flared costochondral junctions and bone-in-bone anomalies in vertebrae); and deficiency of all types of lymphocytes.

Omenn syndrome

It is a rare autosomal recessive disease usually presenting in neonatal period, characterized by symptoms of SCID associated with other findings like erythroderma, lymphadenopathy, hepatosplenomegaly, and eosinophilia.

Treatment

- Pneumocystis prophylaxis with trimethoprim-sulfamethoxazole.
- Replacement IgG therapy. Enzyme replacement therapy [e.g., polyethylene glycol-adenosine deaminase (PEG-ADA)].
- Patients should only be transfused with irradiated blood products and should not receive any live vaccines.

Q. List the clinical features of DiGeorge syndrome.

Features of DiGeorge syndrome (congenital thymic aplasia) are mentioned in **Box 22.6.**

Box 22.6: DiGeorge syndrome (congenital thymic aplasia).

- Defective development in thymus and parathyroid that develop from third and fourth pharyngeal pouch.
- Thymic hypoplasia leading to variable immunodeficiency.
- Characteristic facies. Deletion in 22q11 in >80%.
- **Acronym—CATCH 22**
  - **C**ardiac abnormality (commonly interrupted aortic arch, truncus arteriosus and tetralogy of Fallot)
  - **A**bnormal facies
  - **T**hymic aplasia
  - **C**left palate
  - **H**ypocalcemia/hypoparathyroidism

Wiskott-Aldrich syndrome (WAS)

Q. Write short note on Wiskott-Aldrich syndrome.

- X-linked recessive disease.
- Immunodeficiency, microplatelet thrombocytopenia, and eczema.
- Mutations of the gene encoding WASP at X11p.
- **Low IgM, normal IgA and IgG, and high IgE.**

Ataxia-Telangiectasia

Q. Write short note on ataxia-telangiectasia.

- Autosomal recessive.
- Progressive cerebellar ataxia, abnormal eye movements, oculocutaneous telangiectasias, and immune deficiency. Also characterized by recurrent sinopulmonary infections, bronchiectasis, and interstitial lung disease.
- Vascular malformations (telangiectasia).
- IgA and IgG2 deficiency. T-cell function is variably depressed.
- Gene responsible on **chromosome 11q22.3.**
- Increased serum alfa fetoprotein is diagnostic.
- Prone for various malignancies (lymphomas, breast cancer, and acute leukemias).

Phagocyte Deficiencies

- Chronic granulomatous disease (CGD)
- Leukocyte adhesion deficiency (LAD I)
- **Chediak-Higashi syndrome,** autosomal recessive condition, is characterized by oculocutaneous albinism, easy bruising, abnormal functions of the natural killer cells, and recurrent pyogenic infections and is a result of a mutation in the lysosomal trafficking regulator (*LYST*) gene.
- IL-12/IFNg pathway deficiencies.
- Chronic or cyclic neutropenia.

Diseases of Immune Dysregulation

Four groups of diseases are included in this category.

1. Familial hemophagocytic lymphohistiocytosis (FHL) that includes perforin deficiency. HLH secondary to autoimmune diseases is called macrophage activation syndrome.
2. UNC13D (Munc13–4) deficiency
3. Syntaxin 11 deficiency and STXBP2 (Munc18–2) deficiency
4. Autoimmune lymphoproliferative syndrome (ALPS).

Q. List the clinical features of IgG4-related diseases.

Immunoglobulin G4-related Disease (IgG4-RD)

IgG4-RD is an immune-mediated fibroinflammatory condition affecting multiple organs.

The hallmarks of IgG4-RD are dense lymphoplasmacytic infiltrations with predominance of IgG4-positive plasma cells in the affected tissue, as accompanied by some degree of fibrosis and obliterative phlebitis and increased number of eosinophils.

Clinical Manifestations

Four main clinical phenotypes have been identified.

1. Group 1: Pancreato-hepato-biliary disease
2. Group 2: Retroperitoneal fibrosis/aortitis
3. Group 3: Head and neck limited disease
4. Group 4: Classic Mikulicz syndrome with systemic involvement.

Common manifestations of IgG4-RD include the following, type 1 autoimmune pancreatitis and IgG4-related sclerosing cholangitis, Mikulicz disease, Riedel's thyroiditis, interstitial pneumonitis, and tubulointerstitial nephritis.

Tissue biopsy is the gold standard for the diagnosis which reveals tumor-like swelling of involved organs, a lymphoplasmacytic infiltrate enriched in IgG4-positive plasma cells, variable degree of fibrosis that has a characteristic **"storiform"** pattern. In addition elevated serum concentrations of IgG4 are found in 60–70% of patients.

Treatment

- Glucocorticoids-prednisone
- Rituximab, azathioprine, and methotrexate.

Q. Discuss the clinical presentation and management of cytokine release syndrome.

Cytokine Release Syndrome

Cytokine release syndrome (CRS) is an acute systemic inflammatory syndrome characterized by fever and multiple organ dysfunction that can be triggered by a variety of factors such as infections and certain drugs. It is associated with chimeric antigen receptor (CAR)-T cell therapy, therapeutic antibodies, and haploidentical allogenic transplantation.

CRS was reported in the setting of haploidentical donor stem cell transplantation, graft-versus-host disease. Cytokine storm due to massive T cell stimulation is also a proposed pathogenesis of severe viral infections such as influenza, SARS 2-COVID-19.

Treatment

- Mild CRS of any cause, symptomatic treatment with antihistamines, antipyretics, and fluids
- For severe CRS caused by CART-T cell therapy, initial treatment with tocilizumab plus a corticosteroid rather than single agent alone appears beneficial. Tocilizumab should be given intravenously over 1 hour as follows, patients <30 kg 12 mg/kg, patients >30 kg 8 mg/kg; total tocilizumab dose should not exceed 800 mg. Steroid therapy includes hydrocortisone 100 mg every 8 hours, dexamethasone 10 mg four times daily or methylprednisolone 1 mg/kg/day until there is improvement in CRS.

Clinical Manifestations

- Include fever, which may be accompanied by fatigue, headache, diarrhea, and arthralgia.
- Mild CRS can progress to a more severe syndrome which may include hypotension, hypoxia, and uncontrolled systemic inflammatory response with circulatory collapse, vascular leakage, cardiac dysfunction, and multiorgan system failure.

Q. List the diagnostic criteria of hemophagocytic lymphohistiocytosis.

Hemophagocytic Lymphohistiocytosis

Hemophagocytic lymphohistiocytosis (HLH) is an aggressive and life-threatening syndrome of excessive immune activation. It is most common in infants and young children but can affect patients of any age, with or without a predisposing familial condition. The term **macrophage activation syndrome (MAS)** refers to a form of HLH that occurs primarily in patients with juvenile idiopathic arthritis or other rheumatologic diseases.

Genetic defect: Mutations at familial hemophagocytic lymphohistiocytosis (FHL) loci include PRF1/Perforin, UNC13D/Munc13-4, STX11/Syntaxin11.

Clinical Features

Diagnostic Criteria of HLH-2004

The diagnosis of HLH can be established if one of either 1 or 2 below is fulfilled:

1. A molecular diagnosis consistent with HLH is made.
2. Diagnostic criteria for HLH are fulfilled (5 of the 8 criteria below):
    - Fever
    - Splenomegaly
    - Cytopenias (affecting >2–3 lineages in the peripheral blood):
        - Hemoglobin <9 g/dL (in infants <4 weeks of age, hemoglobin <10 g/dL)
        - Platelets <100 × 10^9/L
        - Neutrophils <1.0 × 10^9/L
    - Hypertriglyceridemia (fasting triglycerides >265 mg/dL) and/or hypofibrinogenemia (fibrinogen <150 mg/ dL)
    - Hemophagocytosis in bone marrow, spleen, or lymph nodes
    - Low or absent NK-cell activity
    - Ferritin >500 ng/mL
    - Elevated soluble CD25 (i.e., sIL2R) two standard deviations above age-adjusted laboratory specific norms.

Treatment

- Among patients who are acutely ill or deteriorating, HLH-94-based therapy includes etoposide and dexamethasone given as tapering doses over 8 weeks, with intrathecal methotrexate and hydrocortisone for those with central nervous system involvement.
- Patients should receive supportive care like transfusions of red blood cells, platelets, and fresh frozen plasma.
- Hematopoietic cell transplantation (HCT) following induction therapy is recommended.
- Refractory or recurrent HLH—emapalumab (interferon gamma blocking antibody) and alemtuzumab (anti-CD52 antibody) can be tried.

HYPERSENSITIVITY REACTIONS

Q. List the types of hypersensitivity reactions.

Q. MI1.10 Describe the immunological mechanisms in immunological disorder hypersensitivity, autoimmune disorders and immunodeficiency states and discuss the laboratory methods used in detection.

Immunologically mediated reactions (hypersensitivity reactions) that may produce in tissue damage are summarized in **Table 22.6 and Figure 22.4.**

TABLE 22.6: Characteristic features of hypersensitivity reactions.

Type	*I (immediate)*	*II (cytotoxic)*	*III (immune complex)*	*IV (delayed)*
Antigens	Pollens, molds, mites, food drugs and parasites	Cell surface or tissue bound	Exogenous (viruses, bacteria, fungi, parasites) autoantigens	Cell/tissue bound
Mediators	IgE and mast cells	IgG, IgM, and complement	IgG, IgM, IgA, and complement	Cytotoxic T-cells, activated macrophage
Time taken for reaction to develop	5–10 minutes	6–36 hours	4–12 hours	48–72 hours

Contd...

Contd...

Type	***I (immediate)***	***II (cytotoxic)***	***III (immune complex)***	***IV (delayed)***
Pathological feature	Edema, vasodilatation, mast cell degranulation, eosinophils	Antibody-mediated damage to target cells	Acute inflammatory reaction (neutrophils), vasculitis	➢ Perivascular inflammation, mononuclear cells, fibrin ➢ Granulomas: Caseation and necrosis in TB
Prototype disorder/diseases produced	➢ Asthma (extrinsic) ➢ Anaphylaxis (systemic and localized) ➢ Urticaria, eczema ➢ Angioedema ➢ Allergic rhinitis ➢ Food allergies	➢ Autoimmune hemolytic anemia, transfusion reactions, hemolytic disease of newborn ➢ Goodpasture's syndrome ➢ Pernicious anemia ➢ Myasthenia gravis	Autoimmune diseases (e.g., SLE, glomerulonephritis, rheumatoid arthritis), serum sickness, Arthus reaction	➢ Tuberculosis ➢ Contact dermatitis ➢ Leprosy ➢ Transplant rejection
Diagnostic tests	➢ Skin-prick tests ➢ Specific IgE in serum	➢ Coombs test ➢ Indirect immunofluorescence	Immune complexes, complement levels	Skin test—erythema induration (e.g., tuberculin test)
Treatment	➢ Antigen avoidance ➢ Antihistamines, corticosteroids (usually topical) ➢ Leukotriene receptor antagonists ➢ Sodium cromoglicate ➢ Epinephrine (adrenaline) for life-threatening anaphylaxis	➢ Exchange transfusion ➢ Plasmapheresis ➢ Immunosuppressives/ cytotoxic drugs	➢ Corticosteroids ➢ Immunosuppressives/ cytotoxic drugs ➢ Plasmapheresis ➢ Anti-TNF antibody, anti-B-cell antibody, anti-CTLA-4 antibody	➢ Immunosuppressives ➢ Corticosteroids, removal of antigen

Ag induces cross-linking of IgE bound to mast cells and basophils with release of vasoactive mediators	Ab detected against cell surface antigens meditates cell destruction via complement activation or ADCC	Ag-Ab complexes deposited in various tissues induce complement activation and an ensuing inflammatory response mediated by massive infiltration of neutrophils	Sensitized T_H1 cells shown above release cytokines that activate macrophages or T_C cells that mediate direct cellular damage. T_H2 cells and CTLs mediate similar responses

FIG. 22.4: Features of hypersensitivity reactions (Gell and Coombs classification).

Urticaria ("Hives")

Q. PE31.12 Discuss the etiopathogenesis, clinical complications and management of urticaria angioedema.

Urticaria (also known as hives) is produced due to localized edema of dermis secondary to a temporary increase in capillary permeability. The term angioedema is used if edema involves subcutaneous or submucosal layers. Classification (causes) of urticaria and/or angioedema is presented in **Table 22.7**.

Etiology and Pathogenesis (Fig. 22.5)

Types: Acute urticaria is the presence of urticaria for less than 6 weeks and chronic if it persists for more than 6 weeks.

Urticaria may be brought out by either immunologic or nonimmunologic mechanisms **(Table 22.7)**. Urticaria is triggered by a wide variety of antigens or by physical stimuli, including cold, pressure, and sunlight. They produce local degranulation of mast cells by various mechanism such as (1) type I hypersensitivity, (2) spontaneous mast cell degranulation (chronic urticarial), (3) chemical mast cell degranulation, (4) autoimmunity (chronic urticaria).

TABLE 22.7: Classification of urticaria and/or angioedema.

Immunologic: ➢ Autoimmune ➢ Immunoglobulin E (IgE)-dependent ➢ Immune complex- mediated ➢ Complement- kinin dependent	**Nonimmunologic reactions:** ➢ Direct mast cell-releasing agents (opiates, antibiotics, curare, D-tubocurarine, radiocontrast media) ➢ Vasoactive stimuli ➢ Agents that alter arachidonic acid metabolism (aspirin and nonsteroidal anti-inflammatory agents, azo dyes, and benzoates)
Physical: Heat, cold, pressure, sun, and water	**Infection:** ➢ Viral hepatitis ➢ Infectious mononucleosis ➢ HIV seroconversion
Idiopathic	**Drugs:** Salicylates, opiates, nonsteroidal anti-inflammatory drugs (NSAIDs), antibiotics

Clinical Manifestation

- Urticaria is common and can be seen in persons of all ages.
- The common triggers are cold, heat, sweating, exercise, pressure, vibration, and sunlight. **Dermographism**, literally "skin writing," is the most common form of physical urticaria.
- Urticarial eruptions may involve any area of the body from the scalp to the soles of the feet.
- Urticarial lesions represent local area of edema involving only the superficial portions of the dermis. On certain body sites (e.g., the lips, hands), the edema spreads deeper into subcutaneous tissue and is referred to as angioedema.
- They are well-circumscribed wheals, pink to light red in color, with erythematous raised serpiginous borders and a blanched center. Size of the lesions varies from one millimeter to several centimeters.
- Almost always pruritic and individual wheals come and go within 24 hours and those lesions lasting up to 6 weeks are called as acute urticaria. If the urticaria recurs over a period of 6 weeks or more it is known as chronic urticaria.
- When individual lesions last more than 36–48 hours and leave postinflammatory hyperpigmentation or palpable purpura, it is called urticarial vasculitis.
- Urticaria may be associated with headache, dizziness, nausea, vomiting, abdominal pain, diarrhea, and arthralgias.

Management

- Management of urticaria depends on its severity and the duration.
- Mild urticaria limited to the skin: Antihistamines (diphenhydramine) or the newer nonsedating agents (terfenadine, cetirizine, and loratadine).
- Severe urticaria: Short-term corticosteroids (up to 1 mg/kg).
- Chronic urticaria: Finding the cause and remove the causative antigen. Antihistamines, omalizumab and cyclosporine for 8–16 weeks, may be beneficial.

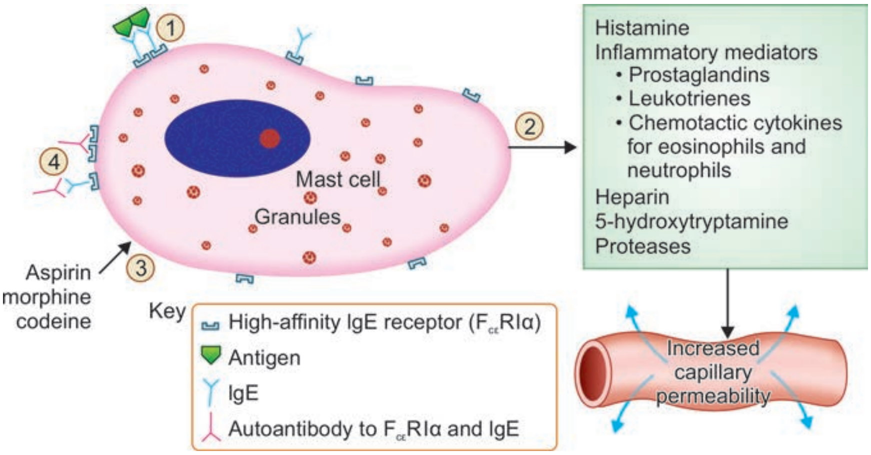

FIG. 22.5: Pathogenesis of urticaria. Mast cell degranulation can occur by different mechanism. (1) Type I hypersensitivity, (2) Spontaneous mast cell degranulation (chronic urticarial), (3) Chemical mast cell degranulation and (4) Autoimmunity (chronic urticaria).

Allergy

Q. Define allergy. List atopic disorders.

- Allergy is defined as a hypersensitivity reaction induced by exposure to an otherwise harmless exogenous substance (known as an allergen), generally environmental.
- In an allergic reaction, initial exposure to allergen triggers the production of specific IgE antibodies by activated B-cells. These IgE antibodies bind to the surface of mast cells via high-affinity IgE receptors.
- The first dose of allergen (priming dose) sensitizes the immunologic system (B lymphocyte). On re-exposure, the allergen (shocking dose) binds to membrane-bound IgE which activates the mast cells, releasing vasoactive mediators (the early phase response), and causing a type I hypersensitivity reaction and the symptoms of allergy. This may be followed by late phase reaction and is mediated by basophils, eosinophils, and macrophages.
- **Examples:** Asthma, anaphylaxis, rhinitis, urticaria, angioedema, eczema, and food hypersensitivity.

Angioedema

Q. Write short essay/note on the clinical features and treatment of angioedema.

Angioedema is defined as a well-demarcated localized edema involving the deeper layers of the skin, including the subcutaneous tissue and submucosal tissues.

Etiology

It is an IgE-mediated reaction that causes direct release of histamine from the mast cells. It follows a variety of allergens. It may develop due to insect sting, drug reaction, food allergy, and exposure to other biological products. Rarely, angiotensin-converting enzyme (ACE) inhibitors may produce angioedema due to increased levels of bradykinin. Most of the cases are idiopathic.

C1-esterase Inhibitor Deficiency

C1-esterase (C1INH) inhibitor is a complement protein that inhibits spontaneous activation of classical complement pathway. C1-esterase inhibitor also regulates kinin cascade, activation of which increases local bradykinin levels and produces local pain and swelling. Both C1-esterase inhibitor and C1 levels are low. C1INH deficiency produces bradykinin. Deficiency of C1INH may be hereditary or acquired disorder.

- **Hereditary angioedema:** It is an autosomal dominant disorder, is due to C1 esterase inhibitor (C1INH) deficiency. Angioedema develops either spontaneously or following infection or injury (e.g., dental injury). Onset is usually in early childhood. The attacks become worse at puberty and usually its frequency and severity decreases after the age of 50 years and may even disappear totally. Diagnosis is confirmed by low levels of C1-esterase inhibitor (in 85% cases) or dysfunctional C1-esterase inhibitor (in 15% cases).
- Mutations in chromosome 11; Autosomal dominant inheritance.
  - Type I C1ID: 85% patients have no detectable protein.
  - Type II C1ID: 15% patients have dysfunctional protein
- **Acquired C1INH deficiency:** It presents in a manner similar to the hereditary angioedema but the onset occurs in the fifth and sixth decades of life. It is due to appearance of an autoantibody. It may occur with B-cell lymphoma, multiple myeloma, Waldenstrom's macroglobulinemia, and chronic lymphocytic leukemia.

Clinical Features

- It may occur at any age but most common in young adults.
- It presents with well-defined, nonpitting swelling, usually nonpruritic. It may be associated with urticaria lesions.
- Angioedema up to 6 weeks is called acute and if it lasts beyond 6 weeks is called chronic.
- It may involve any area of the body but often affects periorbital area, lips **(Fig. 22.6)**, and genital areas.
- Angioedema of the upper respiratory tract may cause laryngeal obstruction which may be life-threatening.

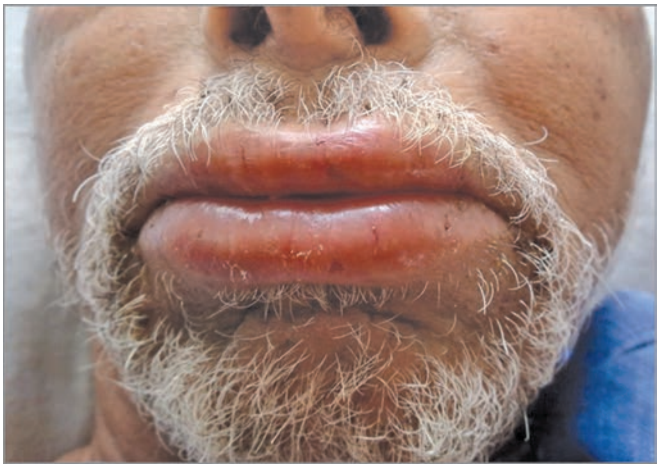

FIG. 22.6: Angioedema.

- Involvement of gastrointestinal system may produce abdominal colic, with or without nausea and vomiting.
- Angioedema does not produce residual discoloration unless there is extravasation of RBCs.

Treatment

- Identification of the etiologic factor(s) and remove the offending agent if possible.
- Antihistamines to control the lesions, e.g., diphenhydramine cetirizine, desloratadine.
- Observe for any evidence of airway obstruction and if present manage in a fashion similar to those with anaphylaxis.
- Acute attack should be controlled with epinephrine.
- Chronic angioedema not responding to maximal dosages of antihistamines, glucocorticosteroids and other immunomodulating agents (e.g., methotrexate, cyclosporine) may be considered.
- During severe attacks of hereditary angioedema due to C1INH deficiency, fresh frozen plasma is lifesaving as it provides C1-esterase inhibitor. Danazol is useful to prevent episodes of hereditary angioedema.
- Newer therapy for hereditary angioedema: Purified C1 inhibitor concentrate, recombinant C1INH—**Conestat alfa,** bradykinin receptor antagonist—**Icatibant** and kallikrein inhibitor—**Ecallantide.**

Systemic Anaphylaxis

Q. Write short note on anaphylactic reactions (anaphylaxis).

Q. Discuss the causes and treatment/management of anaphylactic shock.

Q. IM22.9 Describe the diagnosis initial approach stabilization and therapy of bee sting allergy.

Definition

Systemic anaphylaxis is a life-threatening form of immediate (appears within minutes after systemic exposure to specific antigen) type I hypersensitivity reaction mediated by IgE. It is a systemic response that develops when mast cells (possibly basophils) are provoked to secrete mediators with potent vasoactive and smooth muscle contractile activities.

Causes

It occurs in sensitized individuals and requires prior sensitization to inciting antigen, either alone or in combination with a hapten. It usually occurs when allergen is administered parenterally and it is less likely after oral ingestion, inhalation, or cutaneous or ocular topical contact. The causes of systemic anaphylactic reactions are listed in **Box 22.7**.

Anaphylaxis may be triggered by extremely small doses of antigen, e.g., the minute dose used in skin testing for various forms of allergies.

Box 22.7: Causes of systemic anaphylactic reactions.

Anaphylaxis: IgE-mediated mast cell degranulation

1. **Proteins:**
   - Foreign proteins (e.g., antisera)
   - Foods (peanuts, fish and shellfish, egg, milk, and soya products)
   - Food additives (aspartame, monosodium glutamate)
2. **Drugs:**
   - Antibiotics (penicillins, cephalosporins tetracyclines, trimethoprim-sulfamethoxazole, vancomycin, and nitrofurantoin)
   - Chemotherapeutic agents
   - Hormones (e.g., insulin, vasopressin, and parathormone)
   - Enzymes (chymotrypsin, penicillinase, and streptokinase)
   - Intravenous anesthetic agents (suxamethonium and propofol)
   - Latex
3. **Biological agents:**
   - Blood
   - Tetanus, rabies, and diphtheria antitoxins
   - Antithymocyte globulin
   - Vaccines
4. **Insect bites and stings:**
   - Honeybee (bee venom)
   - Wasps (wasp venom)

Mechanism (Fig. 22.7)

- **Initial exposure to antigen:** The sensitizing antigen (allergen) from its site of entry is presented to T-cells which differentiate into TH2 cells. IL-13 secreted by TH2 cells enhances IgE production by B-cells. IgE gets attached to mast cells and basophils.
- **During subsequent exposure to antigen,** the antigen (allergen) binds to the IgE antibodies previously bound to the mast cells and produces IgE-induced degranulation of mast cells and basophils. It results in the liberation of a number of mediators **(Table 22.8)**. Mediators released by mast cells include preformed mediators (stored in secretory granules) and secondary mediators (newly synthesized products). They are responsible for the pathogenesis of an anaphylactic reaction **(Table 22.8)**.

Anaphylactoid Reactions (Pseudo-allergic Reactions/Non-IgE-mediated)

Q. Write short note on anaphylactoid reactions.

- They are indistinguishable from anaphylactic reactions.
- Most non-IgE-dependent foreign agents do not require antigen processing (sensitization) and can elicit a mast cell activation response on first antigenic exposure itself. However, they may be associated with IgG and IgM antibodies and not IgE. These antibodies activate the complement system through classical pathway and produce activated complement components and

FIG. 22.7: Mechanism of systemic anaphylaxis.

TABLE 22.8: Mast cell mediators in anaphylactic reactions.

Preformed mediators (primary mediators)	*Secondary (newly synthesized) mediators*
1. Vasoactive amines: Histamine 2. Enzymes: Neutral proteases (chymase, tryptase) and several acid hydrolases 3. Proteoglycans: These include heparin (anticoagulant), and chondroitin sulfate 4. Eosinophil chemotactic factor 5. Neutrophil chemotactic factor	1. Lipid mediators: – Leukotrienes B_4, C_4, and D_4. – Prostaglandin D_2 – Platelet-activating factor (PAF) 2. Cytokines: TNF, IL-1, IL-4 and chemokines

TABLE 22.9: Clinical features of systemic anaphylaxis.

Cutaneous	*Respiratory*
➢ Itching (pruritus) ➢ Hives (urticaria) ➢ Skin erythema with or without angioedema ➢ Flushing ➢ Insect stings	➢ Intense bronchospasm resulting in respiratory distress ➢ Dyspnea and wheeze ➢ Laryngeal edema resulting in hoarseness and laryngeal obstruction ➢ Pulmonary edema
Gastrointestinal	***Cardiovascular***
➢ Nausea ➢ Vomiting ➢ Abdominal cramps ➢ Diarrhea	➢ Tachycardia ➢ Hypotension ➢ Arrhythmias ➢ Shock and collapse
Central nervous system	
➢ Confusion ➢ Feeling of impending doom ➢ Apprehension ➢ Metallic taste ➢ Altered levels of consciousness	**Biphasic anaphylaxis** is recurrence of symptoms that develops following the apparent resolution of the initial anaphylactic episode with no additional exposure to the causative agent

TABLE 22.10: Clinical features of systemic anaphylaxis depending on severity.

Severity	*Features*
Mild	Cutaneous features only: Pruritus, erythema, urticaria or mild angioedema
Moderate	The above plus more severe angioedema and/or vomiting, abdominal pain and/or mild dyspnea or tightening of throat
Severe	The above plus respiratory difficulty (laryngeal edema or asthma) and/or hypotension

Box 22.8: Anaphylactoid reactions (Pseudo-allergic reactions/non-IgE-mediated).

Anaphylactoid: Non-IgE-mediated mast cell degranulation

- **Drugs:**
  - Aspirin and nonsteroidal anti-inflammatory drugs (NSAIDs)
  - Vancomycin
  - Narcotics (e.g., codeine, morphine, opiates)
  - Radiocontrast media/dye
- **Physical:**
  - Exercise
  - Exposure to cold
- **Autoimmune**
- **Narcotics/vancomycin**
- **Idiopathic**

may cause direct release of preformed mediators from mast cells and basophils.

- Short-lived because involves only degranulation of mast cells and not cytokine synthesis.
- **Causes:** *Refer* **Box 22.8.**

Clinical Features (Tables 22.9 and 22.10)

The anaphylactic response appears within minutes after systemic exposure to specific antigen.

Diagnostic Criteria for Anaphylaxis

Anaphylaxis is likely when one of the following three criteria occurs:

1. Acute skin and/or mucosal symptoms (e.g., hives, pruritus, flushing, lip/tongue/uvula swelling) and one of the following:
   a. Respiratory symptoms (e.g., wheezing, stridor, shortness of breath, and hypoxia)
   b. Hypotension or associated end-organ dysfunction (e.g., hypotonia, syncope, and incontinence)
2. Exposure to probable allergen and two or more of the following:
   a. Skin/mucosal tissue involvement
   b. Respiratory symptoms
   c. Hypotension or end-organ dysfunction
   d. Persistent gastrointestinal symptoms (e.g., emesis and abdominal pain)
3. Decreased blood pressure after exposure to known allergen for the patient:
   a. *Adults:* Systolic blood pressure <90 mm Hg or >30% decrease in systolic blood pressure
   b. *Infants and children:* Hypotension for age or >30% decrease in systolic blood pressure

Q. **Write short note on treatment of anaphylaxis. List life-saving drugs used in anaphylactic shock.**

Treatment

Anaphylaxis is an acute medical emergency and its early recognition is imperative, since death occurs within minutes to hours after the first symptoms.

- **Prevent further contact with allergen,** e.g., removal of bee sting.
- **Ensure airway patency:** Fatal outcomes in anaphylaxis are mainly due to either airway constriction or hypotension.
- **Oxygen alone via a nasal catheter or with nebulized salbutamol/albuterol,** oxygen 4–6 L/min.
  - If progressive hypoxia develops, either endotracheal intubation or tracheostomy with intermittent positive ventilation is required for oxygen delivery.
- **Administer adrenaline (epinephrine) intramuscularly** into the thigh and is the most critical drug to administer. Earlier administration during the course of an anaphylactic event is better.
  - Adult: 0.3–0.5 mg (0.3–0.5 mL of a 1:1,000 solution) IM in the lateral thigh, repeated at 10- to 15-minute intervals if necessary.
  - Child: 1:1,000 dilution at 0.01 mg/kg or 0.1–0.3 mL administered IM in the lateral thigh, repeated at 10- to 15-minute intervals if necessary.
    - ◆ 0.5 mL of 1:1,000 solution sublingually in cases of major airway compromise or hypotension.
    - ◆ 3–5 mL of 1:10,000 solution via central line.
    - ◆ 3–5 mL of 1:10,000 solution diluted with 10 mL of normal saline via endotracheal tube.
    - ◆ For protracted symptoms that require multiple doses of epinephrine, an IV epinephrine drip may be useful; the infusion is titrated to maintain adequate BP.
- **Administer antihistamines:** They may prevent the progression of urticaria and pruritus, but does not reverse hypotension or tissue edema by directly opposing effects of mast cell activation, e.g., chlorphenamine 10 mg IM or slow IV injection, diphenhydramine, 50–100 mg IM or IV.
- **Administer corticosteroids:** Hydrocortisone 200 mg IV stat (not effective for the acute event as it takes 4 hours to act; but alleviate recurrence of bronchospasm, urticaria, and hypotension).
- **Glucagon** could reverse refractory bronchospasm and hypotension in patients who are taking β-adrenergic antagonists. Recommended dosage is 1–5 mg intravenously bolus slowly over 5 minutes followed by an infusion at 5–15 µg/min titrated to clinical response.
- **Provide supportive treatments:**
  - *Bronchodilators*: They relieve bronchospasm, e.g., nebulized β_2-agonists/salbutamol and aminophylline, 0.25–0.5 g IV.
  - *Hypotension*: Immediately put patient in the Trendelenburg position (prevent progression to anaphylactic shock). Shock is treated with intravenous fluids (if needed with dopamine) to restore or maintain blood pressure. **ECMO** has been tried.

Non-IgE-mediated (idiopathic) anaphylaxis: Usually presents slowly over a few hours. Begins with pruritus of the palms and soles, then progresses to general pruritus, erythema, and urticaria, with diarrhea, abdominal pain, and hypotension. Respiratory symptoms are rare.

Allergen Immunotherapy or Desensitization

- Subcutaneously incremental doses of allergen are given at 1–2 weekly intervals until the top dose is reached. Sublingual immunotherapy has been practiced too.
- Useful for prevention of atopy/anaphylaxis.

Acute Serum Sickness

Q. Write short note on serum sickness.

- It is a systemic immune complex-mediated disease (type III hypersensitivity reaction).
- It was a frequent sequelae to the administration of large amounts of foreign serum (e.g., serum from immunized horses used for protection against diphtheria). But nowadays it is infrequent.
- IgG is produced when a foreign antigen is injected in large quantities. They form soluble immune (antigen-antibody) complexes.

Mechanism

Introduction of antigen → body's immune system responds by synthesizing antibodies after 4–10 days → antibody reacts with antigen, forming soluble complexes that may diffuse into vascular walls and may initiate activation of complement → complement-containing immune complexes generate influx of leukocytes into vessel walls—proteolytic enzymes that can mediate tissue damage are released → immune complex deposition + inflammatory responses are responsible for vasculitic lesions seen.

Clinical Features

Fever, urticaria (at the site of injection), joint pains (arthralgias), lymph node enlargement, and proteinuria appear during this phase. Wherever immune complexes deposit the tissue damage is similar **(Box 22.9)**.

Box 22.9: Lesion produced in acute serum sickness.

- Vasculitis—inflammatory lesion in blood vessels.
- Glomerulonephritis—inflammatory lesion in renal glomeruli.
- Arthritis—inflammatory lesion in the joints.

Treatment

Treatment of acute serum sickness is shown in **Box 22.10.**

AUTOIMMUNITY

Q. Write short essay/note on autoimmunity.

Definition: Autoimmunity is defined as an immune reaction in which body produces autoantibodies and immunologically competent T-lymphocytes against self-antigens.

Mechanisms of Autoimmunity (Fig. 22.8)

Genetic Factors

Role of susceptibility genes: Most autoimmune diseases are complex multigenic disorders and genetic factors have an important role.

- **Runs in families:** The incidence is greater in monozygotic than in dizygotic twins.
- **Association with HLA genes:** Most significant.

Environmental Factors

Role of infections

A variety of microbes may trigger autoimmunity by several mechanisms.

- **Molecular mimicry:** Few viruses and microbes may express antigens that have the antigenic structure similar to self-antigens. Immune responses against them may cross-react with self-tissue and this phenomenon is known as molecular mimicry. Example: **Rheumatic heart disease,** in which antibodies formed against streptococcal bacterial proteins, cross-react with myocardial proteins and cause myocarditis. Molecular mimicry between microbial proteins and host tissues is also found in *Klebsiella* and HLA-B27 in ankylosing spondylitis, coxsackievirus and glutamic acid decarboxylase in insulin-dependent (type l) diabetes mellitus, rheumatoid arthritis, and multiple sclerosis.

Box 22.10: Treatment of acute serum sickness.

- Corticosteroid creams or ointments: Relieve discomfort from itching and rash.
- Antihistamines: May reduce the length of illness and itching.
- NSAIDs: May relieve joint pain.
- Paracetamol: Helpful in relieving fever and muscle pain.
- Medications causing problem should be stopped and future use should be avoided.

FIG. 22.8: Pathogenesis of autoimmunity.

- **Breakdown of anergy:** Tissue necrosis and inflammation produced by microbial infections can cause **up-regulation of co-stimulatory molecules** on APCs. This may favor breakdown of anergy and activation of T-cells.
- **Immune dysregulation:** Normally, T-cells regulate any autoreactive T- and B-cells that have survived clonal deletion. Dysregulation of T-cell function can lead to loss of control and the development of autoimmune disease, e.g., immunodeficiency diseases such as hypogammaglobulinemia and HIV infection are commonly associated with autoimmune phenomena.

Other environmental factors

- **Ultraviolet radiation**
- **Cigarette smoking**
- **Local tissue injury/damage:** Some autoantigens are hidden within the cells or tissues in immunologically privileged sites (e.g., brain or the anterior chamber of the eye). Therefore, the lymphoid cells remain in a state of immunologic ignorance. In this state, lymphoid cells are neither activated nor energized to proteins expressed by these immunologically privileged sites. If the tissue in the privileged site is damaged by trauma or inflammation or tumor, the antigens may be released. These antigens can evoke an autoimmune response, e.g., Dressler's syndrome is an acute pericarditis developing in a patient with myocardial infarction secondary to the production of anti-myocardial antibodies, development of insulin-dependent diabetes in association of coxsackie virus infection, multiple sclerosis, and sympathetic ophthalmia.
- **Drugs:** T-cell bypass is a mechanism by which T-cells help auto reactivation of B-cells instead of suppressing them, e.g., include drug-induced autoimmune responses such as quinine-induced thrombocytopenia.
- **Hormones.**

Classification of autoimmune disorders is presented in **Table 22.11.**

TABLE 22.11: Classification of autoimmune disorders.

Organ specific autoimmune diseases	*Systemic autoimmune diseases*
➢ Type I diabetes mellitus ➢ Goodpasture syndrome ➢ Multiple sclerosis ➢ Grave's disease ➢ Hashimoto's thyroiditis ➢ Autoimmune pernicious anemia ➢ Autoimmune Addison's disease ➢ Vitiligo ➢ Myasthenia gravis	➢ Rheumatoid arthritis ➢ Scleroderma ➢ Systemic lupus erythematosus ➢ Primary Sjögren syndrome ➢ Polymyositis

Therapy of Autoimmune Disease

- Control of symptoms (e.g., nonsteroidal anti-inflammatory drugs for joint pains, fever, etc., in SLE; β-blockers in patients with thyrotoxic features).
- Specific replacement therapy where the organ has been completely destroyed (e.g., thyroid hormone replacement in hypothyroidism).
- Immunosuppressive therapy including corticosteroids, cytotoxic drugs in different forms, different regimens, and different routes.
- Newer and experimental forms of therapy including immunomodulation, e.g., plasmapheresis, intravenous immunoglobulin therapy, and cyclosporin.

ADULT IMMUNIZATION

Q. List common vaccines that are recommended for adults.

Q. MI1.9 Discuss the immunological basis of vaccines and describe the Universal Immunization Schedule.

Screening tools to be checked before vaccination are listed in **Box 22.11.**

Box 22.11: Utilize screening tools; H-A-L-O.

- **H**ealth condition
- **A**ge
- **L**ifestyle
- **O**ccupation

Contraindications for Immunization

- Previous anaphylaxis to a specific vaccine
- History of anaphylaxis to egg protein, neomycin (MMR)
- Live vaccines in pregnancy
- Live vaccines in patients with impaired immunity.

Adverse Effects of Active Immunization

- Mild fever
- Infection (live vaccines)
- Local reaction

- Allergy/anaphylaxis
- Subacute sclerosing panencephalitis (SSPE), demyelination, and brachial neuritis.

Documentation

Provide copy of vaccine information statement (VIS) to patient/documents to be maintained.

- Date of vaccination and next dose
- Vaccine manufacturer
- Lot number
- Dose and site of vaccine
- Vaccinator's initials

The Advisory Committee on Immunization Practices (ACIP) adult immunization, age-based recommendations in India, is presented in **Table 22.12.**

TABLE 22.12: Adult immunization, age-based recommendations in India, 2020.

Vaccine/Age group	*19–26 years*	*27–49 years*	*50–59 years*	*60–64 years*	*>65 years*
Tetanus, diphtheria, pertussis (Tdap)	Substitute one time dose of Tdap with Td, then booster with Td every 10 years				Td booster every 10 years
Human papilloma vaccine	3 doses				
Varicella	2 doses				
Zoster				1 dose	
Measles, mumps, and rubella	1 or 2 doses		1 dose		
Influenza			1 dose annually		
Pneumococcal (polysaccharide)	1 or 2 doses				1 dose
Hepatitis A	2 doses				
Hepatitis B	3 doses				
Meningococcal	1 or more doses				

░ Recommended if some risk factor is present ▒ All persons who meet the age criteria ▓ No recommendation

Adult immunization based on medical and other indications in India is presented in **Table 22.13.**

TABLE 22.13: Adult immunization based on medical and other indications in India, 2020.

Indication		*Immunocompromised conditions (Excluding HIV)*	*HIV infection with CD4 count*		*Diabetes, heart disease, chronic lung disease*	*Asplenia (excluding elective splenectomy disease)*	*Chronic liver disease*	*Kidney failure, end-stage renal disease, on hemodialysis*	*Health-care professionals*
Vaccine	*Pregnancy*		*<200 cells/uL*	*≥200 cells/uL*					
Tetanus, diphtheria, pertussis (Tdap)	Td – 2 doses 4 weeks apart	Substitute one time dose of Tdap with Td, then booster with Td every 10 years							
Human papilloma vaccine		3 doses for females through age 26 years							
Varicella	Contraindication	2 doses							
Zoster	Contraindication	1 dose							
Measles, mumps, and rubella	Contraindication	1 or 2 doses							
Influenza		1 dose annually							1 dose
Pneumococcal (polysaccharide)		1 or 2 doses							
Hepatitis A	2 doses								
Hepatitis B									
Meningococcal	1 or more doses								

░ Recommended if some risk factor is present ▒ All persons who meet the age criteria ▓ Contraindication

Vaccination details are presented in **Table 22.14.**

TABLE 22.14: Vaccination details.

Vaccine	*Recommendation*	*Booster*	*Route*	*Dose*	*Special population/efficacy*
Diphtheria, tetanus, pertussis	18–64 years Three dose series at 0 and 4 weeks, the third 6–12 months after second	Tdap every 10 years	Intramuscular	0.5 mL	92% efficacy. Pregnant women—1 dose in second or third trimester
Measles, mumps, and rubella	>18 years of age should receive at least one dose of MMR if there is no serologic proof of immunity	No	Subcutaneous		Pregnancy to be avoided for at least 4 weeks after vaccination
Influenza	Annual, single dose	Annual	Intramuscular Nasal spray	0.5 mL, 0.25 mL into each nostril	➢ People aged >50 years ➢ Chronic obstructive pulmonary disease (COPD) ➢ Cardiac diseases ➢ Diabetes mellitus, cancer ➢ Immunodeficiency, renal disease ➢ Hemoglobinopathies ➢ Pregnant women ➢ Healthcare providers ➢ Adult household contacts ➢ Travelers to endemic area
Pneumococcal polysaccharide vaccine (PPSV23) and conjugate vaccine (PCV13)	Single dose Aged above 65 years	Can be repeated after 5 years	Intramuscular	0.5 mL	➢ Anatomic asplenia ➢ Sickle cell disease ➢ Immunocompromised persons ➢ Pregnant women with high-risk conditions
Hepatitis B	For immunocompetent adults, administered at 0, 1, and 6 months	A booster if anti-HBs levels decline to <10 mIU/mL and <100 mIU/ mL in patients on dialysis	Intramuscular	1 mL (20 μg)	Protection (anti-HBs antibody titer of 10 mIU/mL or higher) after recombinant vaccine After first dose—20–30%. After second dose—75–80%. After third doses—90–95%
Hepatitis A	Two doses of 1 mL at 6 months interval		Intramuscular	1 mL	Only recommended in: ➢ People who travel to endemic area of hepatitis A ➢ Persons who work with HAV-infected primates or with HAV in a laboratory ➢ Who receive clotting factor concentrates ➢ Food handlers ➢ Chronic liver disease/CKD awaiting transplant ➢ Men who have sex with men
Varicella	<13 years—1 dose; ->13 years—2 doses. Interval between 2 doses should be 4–8 weeks		Subcutaneous	0.5 mL	Healthcare workers; family contacts of immunocompromised persons; high risk of exposure (e.g., teachers, day care employees, military personnel, and international travelers)
Human papilloma virus	Gardasil vaccine, 3 doses—at 0, 2, and 6 months Cervarix vaccine, 3 doses IM—at 0, 1, and 6 months		Intramuscular	0.5 mL	Woman age 26 years or younger or a man age 21 years or younger. The immunization must precede the sexual debut Age for initiation for vaccination to be 10–12 years (females) and 9–12 years (males)
Meningococcal meningitis	Single dose	Nil	Intramuscular	0.5 mL	During an outbreak (HCW, laboratory worker, close contacts). During interepidemic period. To travelers, pilgrims (quadrivalent), people attending fairs and festivals (bivalent 10–14 days prior)

Contd...

Contd...

Vaccine	***Recommendation***	***Booster***	***Route***	***Dose***	***Special population/efficacy***
Herpes zoster	Single dose	Nil	Subcutaneous	0.65 mL	➢ Recommended for persons >60 years ➢ High risk for developing recurrent herpes zoster, such as: – Patients with chronic medical conditions (CKD, diabetes mellitus, rheumatoid arthritis, and chronic pulmonary disease) – Persons who are likely to have severe immunosuppression in near future
Haemophilus influenzae type b (Hib)			Intramuscular	0.5 mL	Not recommended for routine practice
Typhoid: ➢ Live oral Ty21a vaccine ➢ Injectable Vi polysaccharide vaccine, and Vi-rEPA vaccine		Every 5 years			Not recommended for routine practice
Cholera	Two separate doses, 1–6 weeks apart for those aged over 6 years	No	Oral		85–90% protection

AMYLOIDOSIS

Q. Discuss the classification, clinical features and management of amyloidosis.

Definition: Amyloidosis is a group of acquired and hereditary disorders characterized by extracellular deposition of insoluble polymeric **proteins** fibrils in tissues and organs.

Classification of Amyloidosis (Table 22.15)

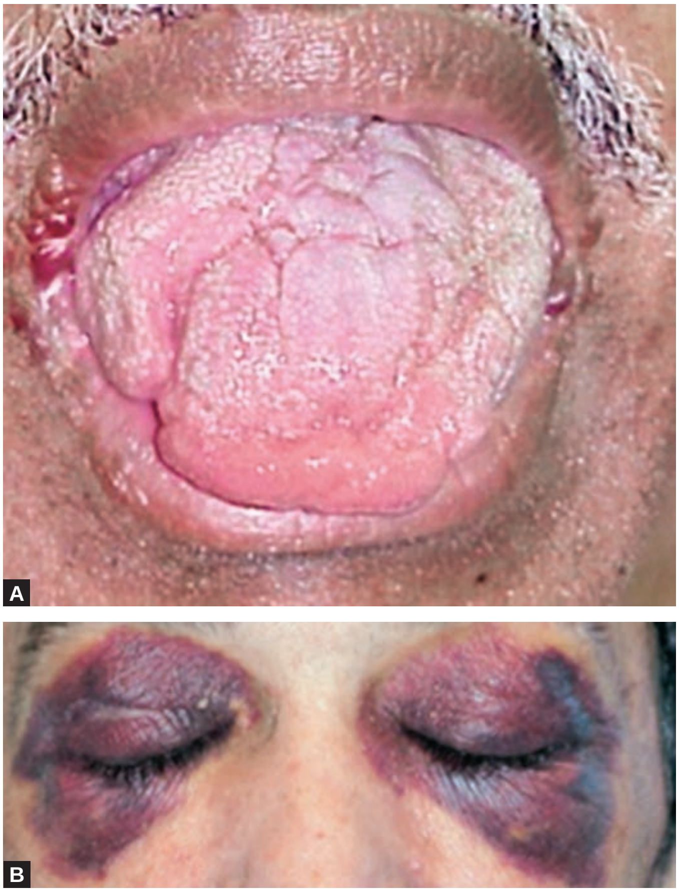
TABLE 22.15: Classification of amyloidosis.

Category	***Precursor protein***	***Fibril protein***	***Associated disease/(s)***
A. Systemic (generalized) amyloidosis			
1. Immunocyte dyscrasias with amyloidosis (primary amyloidosis)	Immunoglobulin light chains (mainly λ)	AL	Multiple myeloma, other plasma cell dyscrasias
2. Reactive systemic amyloidosis (secondary amyloidosis)	Serum amyloid associated (SAA)	AA	Chronic inflammatory process
3. Hemodialysis-associated amyloidosis	β_2-microglobulin	$A\beta_2m$	Chronic renal failure
B. Hereditary or familial amyloidosis			
1. Familial Mediterranean fever	SAA	AA	
2. Familial amyloidotic neuropathies 3. Systemic senile amyloidosis	Transthyretin	ATTR	
C. Localized amyloidosis			
1. Senile cerebral	Amyloid precursor protein (APP)	Aβ	Alzheimer disease
2. Endocrine			
– Thyroid	Calcitonin	A Cal	Medullary carcinoma
– Islets of Langerhans	Islet amyloid peptide	AIAPP	Type 2 diabetes

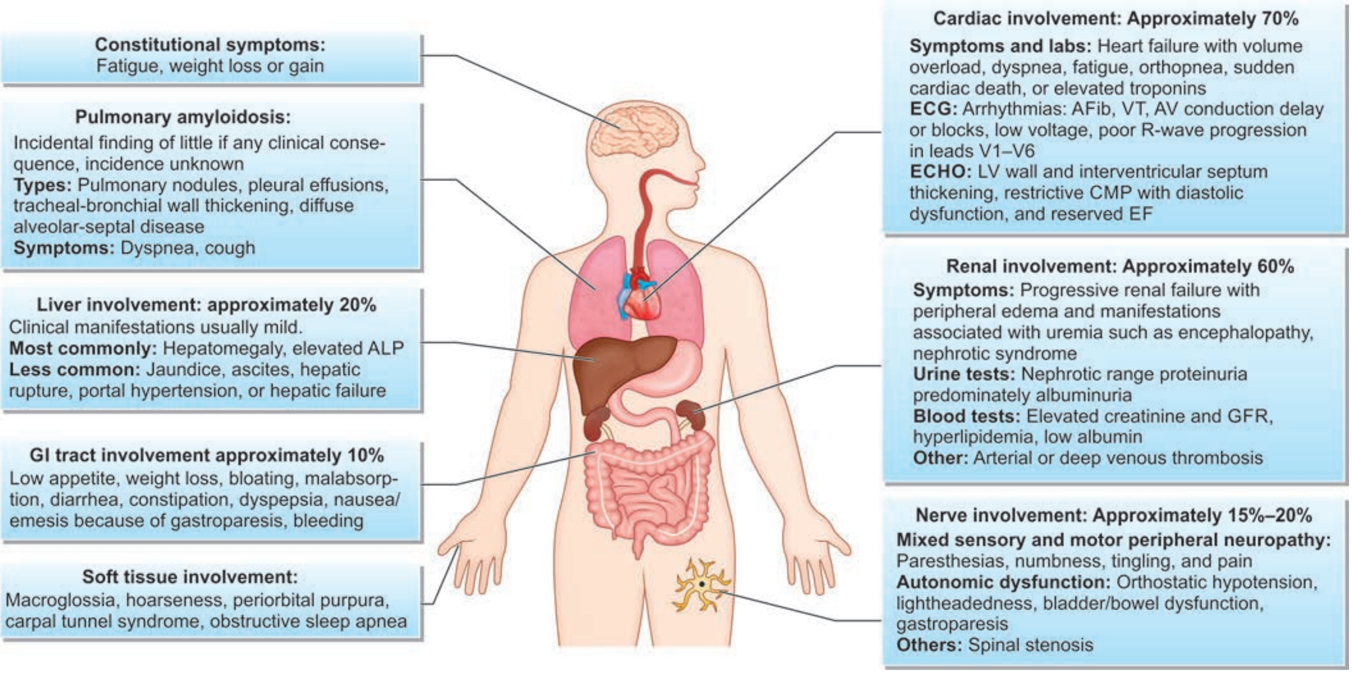
Clinical Features

- It is usually a rapidly progressive disease. The clinical features depend on the organs involved.
- **Nonspecific symptoms:** These include fatigue and weight loss.

- **Renal amyloidosis:** Kidneys are affected in about 70% of patients. It usually presents with proteinuria (often in the nephrotic range), hypoalbuminemia, secondary hypercholesterolemia, and edema or anasarca.
- **Cardiac amyloidosis:** The heart is the second most commonly (50%) affected organ and may show concentric thickening of ventricles and diastolic dysfunction, leading to a restrictive cardiomyopathy. It may present with heart failure.
- **Neuropathies:** Autonomic dysfunction with gastrointestinal motility disturbances (diarrhea, constipation) and peripheral sensory neuropathies are relatively common. Carpal tunnel syndrome with weakness and paresthesia of the hands may be an early presenting feature.
- **Macroglossia (Fig. 22.9A):** Enlarged tongue is pathognomonic of AL amyloidosis that may be found in ~10% of patients.
- **Amyloidosis of liver:** It causes cholestasis and hepatomegaly.
- **Amyloidosis of spleen:** It may produce functional hyposplenism in the absence of significant splenomegaly.
- **Cutaneous amyloidosis:** It can produce:
  - Easy bruising due to amyloid deposits in capillaries or due to deficiency of clotting factor X, which can bind to amyloid fibrils.
  - Cutaneous ecchymosis especially around the eyes and can produce "raccoon-eye" sign **(Fig. 22.9B)**.
- **Other findings:** These include nail dystrophy, alopecia, and amyloid arthropathy with thickening of synovial membranes in wrists and shoulders **(Fig. 22.10)**.



FIGS. 22.9A AND B: (A) Macroglossia; (B) Racoon eyes in amyloidosis.



Constitutional symptoms:
Fatigue, weight loss or gain

Pulmonary amyloidosis:
Incidental finding of little if any clinical consequence, incidence unknown
Types: Pulmonary nodules, pleural effusions, tracheal-bronchial wall thickening, diffuse alveolar-septal disease
Symptoms: Dyspnea, cough

Liver involvement: approximately 20%
Clinical manifestations usually mild.
Most commonly: Hepatomegaly, elevated ALP
Less common: Jaundice, ascites, hepatic rupture, portal hypertension, or hepatic failure

GI tract involvement approximately 10%
Low appetite, weight loss, bloating, malabsorption, diarrhea, constipation, dyspepsia, nausea/emesis because of gastroparesis, bleeding

Soft tissue involvement:
Macroglossia, hoarseness, periorbital purpura, carpal tunnel syndrome, obstructive sleep apnea

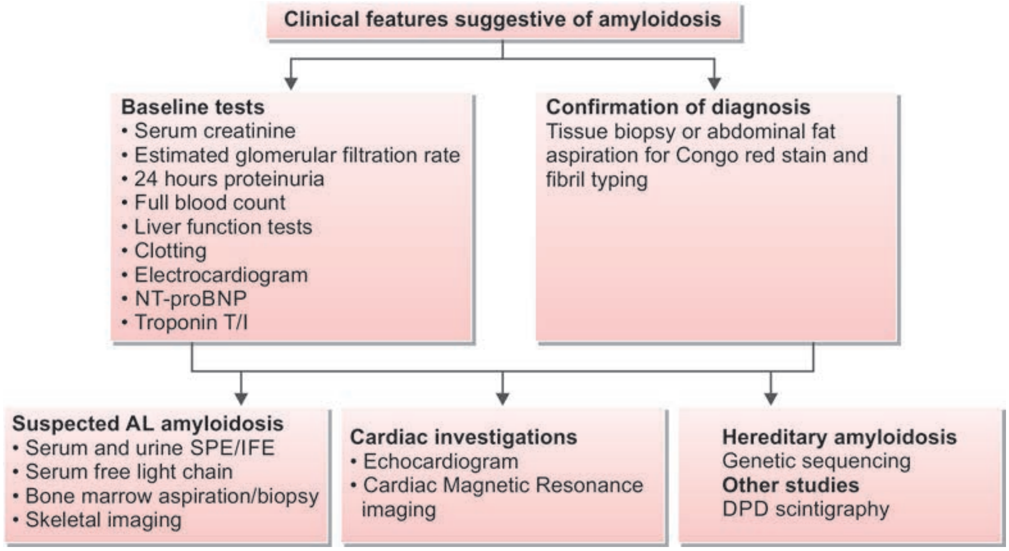
Cardiac involvement: Approximately 70%
Symptoms and labs: Heart failure with volume overload, dyspnea, fatigue, orthopnea, sudden cardiac death, or elevated troponins
ECG: Arrhythmias: AFib, VT, AV conduction delay or blocks, low voltage, poor R-wave progression in leads V1–V6
ECHO: LV wall and interventricular septum thickening, restrictive CMP with diastolic dysfunction, and reserved EF

Renal involvement: Approximately 60%
Symptoms: Progressive renal failure with peripheral edema and manifestations associated with uremia such as encephalopathy, nephrotic syndrome
Urine tests: Nephrotic range proteinuria predominately albuminuria
Blood tests: Elevated creatinine and GFR, hyperlipidemia, low albumin
Other: Arterial or deep venous thrombosis

Nerve involvement: Approximately 15%–20%
Mixed sensory and motor peripheral neuropathy: Paresthesias, numbness, tingling, and pain
Autonomic dysfunction: Orthostatic hypotension, lightheadedness, bladder/bowel dysfunction, gastroparesis
Others: Spinal stenosis

FIG. 22.10: Clinical features of amyloidosis.

FLOWCHART 22.1: Diagnostic stepwise approach to suspect amyloidosis.



Clinical features suggestive of amyloidosis
Baseline tests
• Serum creatinine
• Estimated glomerular filtration rate
• 24 hours proteinuria
• Full blood count
• Liver function tests
• Clotting
• Electrocardiogram
• NT-proBNP
• Troponin T/I
Confirmation of diagnosis
Tissue biopsy or abdominal fat aspiration for Congo red stain and fibril typing
Suspected AL amyloidosis
• Serum and urine SPE/IFE
• Serum free light chain
• Bone marrow aspiration/biopsy
• Skeletal imaging
Cardiac investigations
• Echocardiogram
• Cardiac Magnetic Resonance imaging
Hereditary amyloidosis
Genetic sequencing
Other studies
DPD scintigraphy

(AL: Amyloid light-chain; DPD: 3,3-diphosphono-1,2-propanodicarboxylic acid; IFE: Immunofixation electrophoresis; NT-proBNP: N-terminal pro-brain natriuretic peptide; SPE: Serum protein electrophoresis).

Diagnosis (Flowchart 22.1)

Key feature for diagnosis of AL amyloidosis is the identification of the underlying B-lymphoproliferative process and clonal light chain.

Serum protein electrophoresis (SPEP) and urine protein electrophoresis (UPEP) are NOT useful screening tests. However, more than 90% of cases show serum or urine monoclonal LC or whole immunoglobulin by immunofixation electrophoresis of serum (SIFE) or urine (UIFE).

Heredofamilial Amyloidosis

1. Familial Mediterranean Fever

- **Autosomal recessive** disorder.
- Characterized by recurrent attacks of fever accompanied with inflammation of serosal surfaces (peritoneum, pleura, and synovial membrane).

2. Familial Amyloidotic Neuropathies

- Familial amyloidotic neuropathies are characterized by **deposition of amyloid in peripheral and autonomic nerves** and the **fibrils are made up of mutant TTRs.**
- **ATTR (transthyretin associated)** amyloidosis is transmitted as autosomal dominant disease.
- Clinically, they present with peripheral sensorimotor and autonomic neuropathy and symptoms of autonomic dysfunction, diarrhea, and weight loss. Renal involvement is less common than with AL amyloidosis. Macroglossia does not develop.

Hemodialysis-associated (Dialysis-related) Amyloidosis

- Patients with **chronic renal failure** (ESRD) **on long-term hemodialysis** have high **levels of β_2-microglobulin** in the serum because it cannot be filtered through dialysis membrane and gets deposited as amyloid. Its incidence appears to be decreasing with newer high-flow dialysis techniques.
- It produces rheumatologic manifestations and usually presents with carpal tunnel syndrome, persistent joint effusions, spondyloarthropathy, or cystic bone lesions.

Other Amyloids

- **Cerebral amyloidosis:** Brain is a common site of amyloid deposition, though it is not directly affected in any form of acquired systemic amyloidosis.
- **Alzheimer's disease:** Intracerebral and cerebrovascular amyloid deposits are found in Alzheimer's disease. Most cases are sporadic.
- **Transmissible spongiform encephalopathy:** In hereditary spongiform encephalopathies, several amyloid plaques are observed.

Treatment

- **Aim of treatment:** To support the function of affected organs and, in acquired amyloidosis, treatment of the associated primary disorder to prevent further amyloid deposition.
- **Treatment of underlying disorder:** Treatment of any underlying inflammatory source or infection may produce regression of existing amyloid deposits. Chemotherapy with melphalan plus dexamethasone or stem cell therapy is useful in AL amyloidosis.
- Second-line chemotherapy includes thalidomide/lenalidomide, bortezomib, carfilzomib plus dexamethasone.
- Colchicine may be useful in familial Mediterranean fever.
- Nephrotic syndrome and congestive cardiac failure are treated with the relevant therapies.
- Hereditary transthyretin amyloidosis: In ATTR amyloidosis, where transthyretin is mainly produced in the liver, liver transplantation is the definitive therapy.

Treatment	Line of therapy
Autologous stem cell transplant (ASCT)	(1) Upfront transplant (in selected cases); (2) Consolidation after induction
Alkylating agent (melphalan) and dexamethasone	
Melphalan and Dex (M-Dex)	First-line therapy in selected transplant ineligible patients
Proteasome inhibitor therapy	
Bortezomib	Backbone therapy for various combinations
Bortezomib, cyclophosphamide, dexamethasone (CyBorD)	First line or relapse AL amyloidosis (can be considered for both transplant eligible and ineligible
Bortezomib, melphalan, dexamethasone (BMDex)	First line or relapse AL amyloidosis (transplant ineligible patients)
Bortezomib, lenalidomide, dexamethasone (VRd)	Use is limited to selected patients with t11:14, no cardiac involvement, no history solid organ transplant
Carfilzomib	Not recommended outside of clinical trial
Ixazomib	
Ixazomib + dexamethasone	Relapse/refractory AL amyloidosis after one or more prior lines of therapy
Ixazomib + cyclophosphamide + dexamethasone	Investigational
Immunomodulatory drugs	
Thalidomide	
Thalidomide, dexamethasone	(1) Rarely used due to toxicity; (2) Not commonly prescribe in USA
Thalidomide, cyclophosphamide, dexamethasone	(1) Use in relapse AL amyloidosis (case by case basis); (2) Not commonly prescribe in the USA
Lenalidomide	
Lenalidomide-dexamethasone	Limited to selected cases for both first line and relapse AL amyloidosis
Lenalidomide, cyclophosphamide, dexamethasone	Limited to selected cases for both first line and relapse AL amyloidosis
Pomalidomide	
Pomalidomide-dexamethasone	(1) Preferred over lenalidomide and dexamethasone; (2) Use is limited to relapse AL amyloidosis
Monoclonal antibodies targeting CD38	
Daratumumab (IV)	Heavily pretreated AL amyloidosis
Daratumumab (SQ), bortezomib, cyclophosphamide, dexamethasone	Recommended as first line induction therapy both in transplant eligible and transplant ineligible patients (preferred)
Ixazomib + daratumumab + dexamethasone	Investigational
Daratumumab, pomalidomide	Investigational
Isatuximab	Investigational
Targeting amyloid component therapy	
NEOD001	Investigational
CAEL-101	Investigational
Antimetabolite and alkylating agent	
Bendamustine	Investigational
Small molecules	
Doxycycline	Consider doxycycline as an adjuvant to standard chemotherapy
Venetoclax (BCL-2 inhibitor)	Investigational
Epigallocatechin-3-gallate (ECGC)	Investigational
Ibrutunib [bruton tyrosine kinase (BTK) inhibitor]	Investigational
Oncopeptides	
Melflufen + dexamethasone	Investigational

CHAPTER

23

Genetics

COMMON GENETIC AND CHROMOSOMAL DISORDERS

Q. Write short essay/note on various types (classification) of chromosomal disorders/aberrations.

Classification of Chromosomal Disorders (Box 23.1)

Numerical Chromosomal Aberrations

Normal cells are **diploid** containing 46 chromosomes, 22 pairs of autosomes and 1 pair of sex chromosomes. The 23 chromosomes (22 autosomes and one sex chromosome) constitute a **haploid**. Any exact multiple of the haploid number is called **euploid**.

Types of numerical aberrations

Aneuploidy: It is defined as a **chromosome number that is not a multiple of 23** (the normal haploid number). It is caused by either loss or gain of one or more chromosomes. Aneuploidy may result from **nondisjunction or anaphase lag**.

- **Trisomy:** Numerical abnormalities with the presence of **one extra chromosome** are referred to as trisomy (2n + 1). It may involve either **sex chromosomes or autosomes**. *Examples:* Down syndrome (patients have three copies of chromosome 21, i.e., 47 XX, +21, hence Down syndrome is often known as trisomy 21), Patau syndrome (trisomy 13; 47 XY, +13), and Edwards syndrome (trisomy 18; 47 XY, +18).
- **Monosomy:** Numerical abnormalities with the **absence or loss of one chromosome** (2n – 1) are referred to as monosomy. It may involve autosomes or sex chromosomes. Monosomy of autosomes is almost incompatible with survival. *Example:* For monosomy of sex chromosomes is Turner syndrome **(45 XO)** instead of normal XX (46 XX).

Polyploidy: It is chromosome number that is a multiple greater than two of the haploid number (multiples of haploid number 23). Triploidy is three times the haploid number (69), tetraploidy is four times the haploid number (92). Polyploidy is incompatible with life and usually results in spontaneous abortion.

Causes of numerical aberrations

- Numerical aberrations can occur during meiosis and/or mitosis. These errors are due to nondisjunction and anaphase lag.
- **Nondisjunction:** It is failure of paired chromosomes to separate during meiosis or mitosis. Meiotic nondisjunction is the most common cause.
- **Anaphase lag:** Anaphase lag results in the loss of a chromosome during meiosis or mitosis.

Box 23.1: Types of chromosomal abnormality.

Numerical abnormalities
- **Aneuploidy**
  - Monosomy
  - Trisomy
  - Tetrasomy
- **Polyploidy**
  - Triploidy
  - Tetraploidy

Structural abnormalities
- Translocations (exchange)
- Deletions (loss)
- Duplications
- Insertions
- Inversions
- Nondisjunction
- Ring chromosome

Isochromosomes

Mixoploidy
- Mosaicism
- Chimerism

Structural Chromosomal Aberrations (Box 23.1)

Q. Discuss chromosomal translocations with examples.

Q. What is reciprocal translocation?

Q. Write a note on Robertsonian translocation.

Structural chromosomal aberrations may occur either during **mitosis** or **meiosis**.

Causes of structural alterations: It may occur spontaneously at a low rate and is increased by exposure to environmental mutagens, such as chemicals and ionizing radiation.

Types of Structural/Chromosomal Aberrations (Figs. 23.1A to H)

Translocations: It is a structural alteration between two chromosomes in which a **segment of one chromosome gets detached and is transferred to another chromosome**. There are two types of translocations:

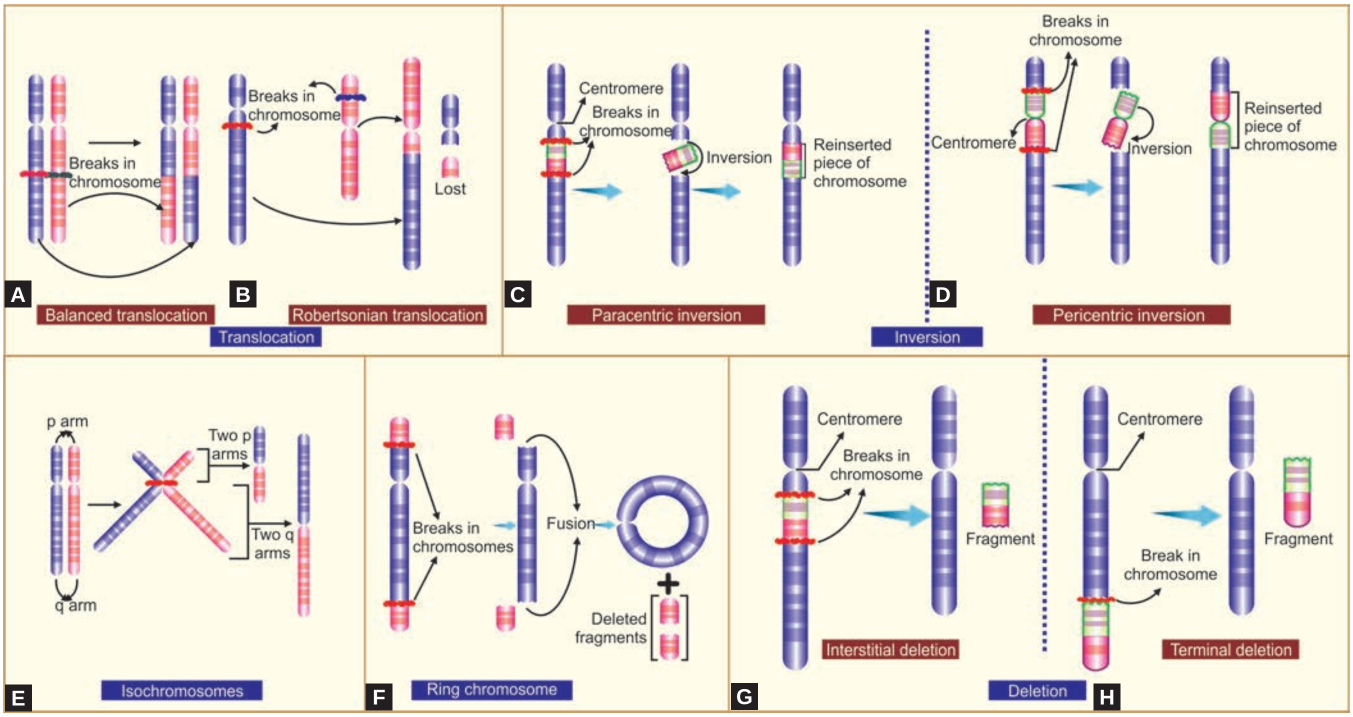
1. **Balanced reciprocal translocations:** It is characterized by single break in each of the two chromosomes with exchange of genetic material distal to the break. There is no loss of genetic material. A balanced reciprocal translocation between the long arm of chromosome 5 and the short arm of chromosome 10 would be written *46, XX, t (5; 10) (q31; p14).*
   - **Simple translocation:** In this case, terminal segment of a chromosome is integrated at one end of a nonhomologous region. Simple translocations are rather rare.
   - **Shift:** In shift, an intercalary segment of a chromosome is integrated within a nonhomologous chromosome.
2. **Robertsonian translocation/centric fusion:**
   - This results from the breakage of two acrocentric chromosomes (i.e., chromosome **13, 14, 15, 21, 22)** at or close to their centromeres and subsequent fusion of their long arms.
   - The short arms of each chromosome are lost, this being of no clinical importance as they contain genes only for ribosomal RNA, for which there are multiple copies on various other chromosomes.
   - The total chromosome number is reduced to **45**.
   - The overall incidence of this translocation is 1 in 1,000, the most common being 13q14q.
   - The major practical importance is that this can predispose to the birth of babies with Down syndrome.

Inversion: When a segment of chromosome is oriented in the reverse direction, such segment said to be inverted and the phenomenon is termed as inversion.

Isochromosomes: They are formed **due to faulty centromere division**. Normally, centromeres divide in a plane parallel to long axis of the chromosome. If a centromere divides in a plane transverse to the long axis, it results in pair of isochromosomes. One pair consists of two short arms and the other of two long arms.

Deletion: It is **the loss of a part of a chromosome**. It is of two types namely: (1) interstitial (middle) and (2) terminal (rare).

- **Interstitial deletion:** It occurs when there are two breaks within a chromosome arm. This is followed by loss of the chromosomal material between the breaks and fusion of the broken ends of the remaining portion of the chromosome. It has to be specified in which region(s) and at what bands the breaks have occurred. For example, *46, XY, del (16)*



Breaks in chromosome
Breaks in chromosome
Lost

H
Deletion

FIGS. 23.1A TO H: Types of structural abnormalities of chromosome.

(p11.2p13.1) describes breakpoints in the short arm of chromosome 16 at 16p11.2 and 16p13.1 with loss of material between breaks.

- **Terminal deletion:** It results from a single break at the terminal part in a chromosome arm, producing a shortened chromosome bearing a deletion and a fragment with no centromere. The fragment is then lost at the next cell division.

Ring chromosome: It is a **special form of deletion**. Ring chromosomes are formed by a break at both the ends of a chromosome with fusion of the damaged ends.

Insertion: It is a form of **nonreciprocal translocation** in which a fragment of chromosome is transferred and inserted into a nonhomologous chromosome.

Mixoploidy

Mosaicism: Defined as the presence in an individual, or in a tissue, of two or more cell lines that differ in their genetic constitution but are derived from a single zygote, i.e., they have the same genetic origin. Seen in Down syndrome (1–2%) and Duchenne muscular dystrophy.

Chimerism: Defined as the presence in an individual, or in a tissue, of two or more cell lines that are derived from more than one zygote, i.e., they have different genetic origin.

DOWN SYNDROME (TRISOMY 21)

Q. PE32.1 **Discuss the genetic basis, risk factors, complications, prenatal diagnosis, management and genetic counseling in Down's syndrome.**

The best known and most common chromosome related syndrome. Formerly known as "Mongolism".

It is the most common chromosomal disorder and is a leading cause *of mental retardation*. The incidence of Down syndrome in newborns is about 1 in 700 live births.

Etiology and Pathogenesis

- **Maternal age:** It has a **strong influence** on the incidence of trisomy 21. Children of older mothers have much greater risk of having Down syndrome. The risk for mothers < 25 years of age to have the trisomy is about 1 in 1,500 births. At 40 years of age, 1 in 100 births. At 45 years, 1 in 40 births.
- **Other factors:** Increased incidence may be associated with exposure of mother to pesticides, electromagnetic fields, anesthetic drugs, alcohol, and caffeine.

Mechanism of trisomy 21: The three copies of chromosome 21 in somatic cells cause Down syndrome. It may be due to:

1. About 95% of these individuals have *nondisjunction* during the first meiotic division of gametogenesis.
2. *Robertsonian translocation* of an extra long arm of chromosome 21 to another acrocentric chromosome causes about 5% of cases.
3. About 1% *mosaicism* having two different cell lines, one with normal chromosomal constitution and the other with an extra chromosome 21.

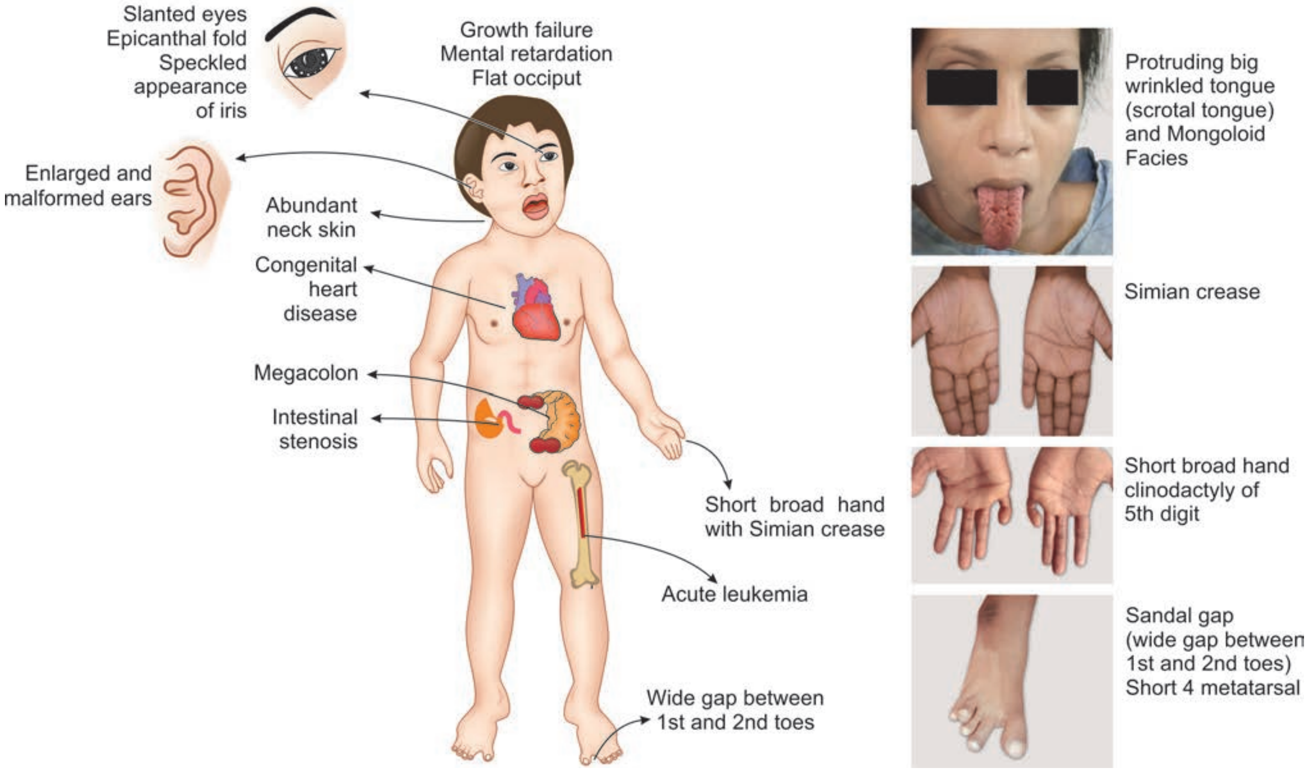
Clinical Features (Fig. 23.2)

Craniofacial and Skeletal Features

- Flat face and occiput, with a low-bridged nose, reduced interpupillary distance and oblique palpebral fissures.
- Epicanthal folds of the eyes impart an almond shape to the eyes and an oriental appearance (obsolete term mongolism).
- A speckled appearance of the iris (brushfield spots), enlarged and malformed ears.
- A protruding furrowed tongue (macroglossia), which typically lacks a central fissure and protrudes through an open mouth (scrotal tongue).
- Broad, short neck, brachycephaly, Simian crease-single palmar flexion crease (50% cases), clinodactyly-incurved fifth finger with hypoplastic mid phalanx (60%), short stature, hypotonia and space between the first and second toes (sandal gap).

Brain: Mild to moderate intellectual **disability**, attention-deficit hyperactivity disorder, autism, dementia, atlantoaxial dislocation.

Heart: Congenital **cardiac anomalies** are responsible for the majority of the deaths in infancy and early childhood. The genetic band in 21q22 critical region is considered responsible for the cardiac anomalies. Complete atrioventricular septal defect (CAVSD)—37%, ventricular septal defect (VSD)—31%, atrial septal defect (ASD)—15%, partial atrioventricular septal defect (PAVSD)—6%, and patent ductus arteriosus (PDA)—4%.



Slanted eyes
Epicanthal fold
Speckled appearance of iris
Growth failure
Mental retardation
Flat occiput
Enlarged and malformed ears
Abundant neck skin
Congenital heart disease
Megacolon
Intestinal stenosis
Short broad hand with Simian crease
Acute leukemia
Wide gap between 1st and 2nd toes
Protruding big wrinkled tongue (scrotal tongue) and Mongoloid Facies
Simian crease
Short broad hand clinodactyly of 5th digit
Sandal gap (wide gap between 1st and 2nd toes) Short 4 metatarsal

FIG. 23.2: Major clinical features of Down syndrome.

Gastrointestinal tract: It may show esophageal/duodenal stenosis or atresia, imperforate anus and Hirschsprung disease (megacolon).

Genitourinary: Hypospadias, cryptorchidism. Males are infertile due to impaired spermatogenesis.

Immune system: Affected children are susceptible to infections due to defective immunity.

Endocrine system: Antithyroid antibodies may cause hypothyroidism and type 1 diabetes.

Hematologic disorders: They have increased risk of acute myeloid or lymphoblastic leukemia. Polycythemia, macrocytosis, leukopenia, and leukemia (acute megakaryoblastic, and acute lymphoblastic).

Other features: Refractive errors, strabismus, sensorineural hearing loss, obesity, obstructive sleep apnea, palmoplantar hyperkeratosis, juvenile idiopathic arthritis.

Down syndrome screens are mentioned in **Box 23.2**.

Box 23.2: Down syndrome screens.

- **Triple screen (75% sensitive):** Maternal serum alpha-fetoprotein, estriol, and human chorionic gonadotropin.
- **Quad screen (79% sensitive):** Maternal serum alpha-fetoprotein, estriol, human chorionic gonadotropin, and high inhibin-alpha (INHA).
- **Nuchal translucency/free beta-hCG>/PAPPA screen (91% sensitive):** Ultrasound to measure nuchal translucency in addition to the free Beta-hCG and PAPPA (pregnancy-associated plasma protein A).
- **The full integrated test** (first-trimester nuchal translucency and PAPPA plus second-trimester quadruple markers) detects 85% of Down syndrome fetuses.

KLINEFELTER SYNDROME

Q. PE32.11 Discuss the genetic basis, risk factors, complications, prenatal diagnosis, management and genetic counseling in Klinefelter syndrome.

It is an important genetic cause of male hypogonadism and is associated with reduced spermatogenesis and male infertility.

Pathogenesis

- Most patients with Klinefelter syndrome have one extra X chromosome (47, XXY karyotype). It is due to *nondisjunction* of X chromosome during meiosis.

- A minority is mosaic (e.g., 46, XY/47, XXY) or has more than two X chromosomes (e.g., 48, XXXY) and one or more Y chromosomes.

Clinical Features (Fig. 23.3)

- Klinefelter syndrome is usually diagnosed after puberty.
- Most patients are **tall and thin** with relatively long legs (eunuchoid body habitus). Mental retardation is uncommon, although average intelligence quotient (IQ) is reduced.
- At puberty, **testes and penis remain small with lack of secondary male characteristics**.
  - Female characteristics develop which include a **high-pitched/deep voice, gynecomastia,** and a **female pattern of pubic hair**. Sparse facial, body and sexual hair.
  - **Azoospermia** results in infertility.

All of these changes are due to hypogonadism and reduced levels of testosterone.

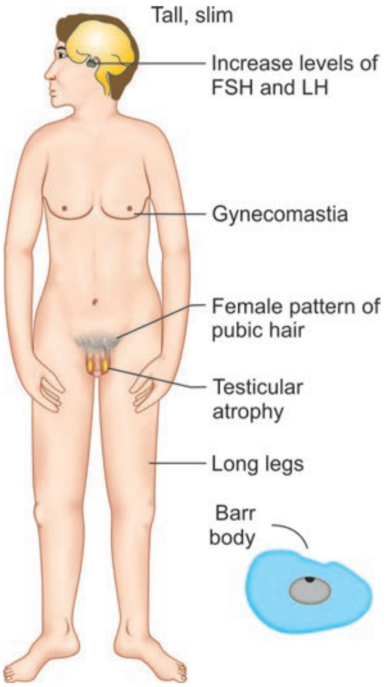


FIG. 23.3: Clinical features of Klinefelter syndrome.

Diagnosis

- **Buccal smear for Barr body:** Extra X chromosome may be seen as a Barr body on buccal smears.
- **Nuclear sexing of leukocytes: Neutrophils** in the peripheral smear may also be examined for nuclear sexing. In a normal female (XX), the neutrophils in a peripheral smear show a drumstick which is counterpart of Barr body in buccal smear. One extra drumstick is found in males with *Klinefelter syndrome* (XXY).
- Chromosomal analysis
- **Hormonal status:**
  - Follicle-stimulating hormone (FSH) and luteinizing hormone (LH) are remarkably high.
  - *Testosterone:* Low to low-normal level.
  - The ratio of estrogens and testosterone determines the degree of feminization. Complications of Klinefelter syndrome are listed in **Box 23.3**.

Box 23.3: Complications of Klinefelter syndrome.

- Increased **risk of breast carcinoma** in 47, XXY (relative risk exceeding 200 times).
- **Endocrine complications:** Diabetes mellitus, hypothyroidism and hypoparathyroidism.
- **Autoimmune diseases:** Systemic lupus erythematosus, Sjogren's syndrome and rheumatoid arthritis.
- **Decreased bone density:**
  - Increased risk of ischemic heart disease, mitral valve prolapse, lower extremity varicose veins, venous stasis ulcers, and deep venous thrombosis and pulmonary embolism
  - Extragonadal germ cell cancer and non-Hodgkin lymphoma occur in more frequency

Management

- *Testosterone:* It should be started at puberty (around 12 years age) and increasing its dosage sufficient to maintain serum concentrations of testosterone, estradiol, FSH, and LH appropriate to the age. It promotes normal body proportions and development of normal secondary sex characteristics. However, it does not affect infertility, gynecomastia, and atrophy of testis. It decreases the long-term complications such as breast cancer, autoimmune disease, and osteoporosis.
- Speech therapy.
- Physiotherapy for hypotonia or delayed motor skills.

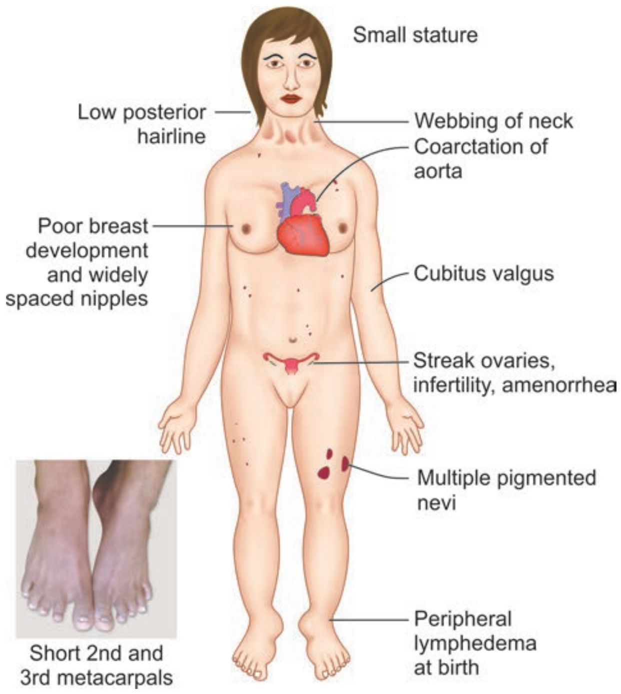
TURNER SYNDROME

Q. PE32.6 Discuss the genetic basis, risk factors, clinical features, complications, prenatal diagnosis, management and genetic counseling in Turner's syndrome.

- Turner syndrome is a sex chromosomal abnormality. Turner syndrome is characterized by a spectrum of abnormalities due to **complete or partial monosomy of the X chromosome** in a phenotypic female.
- It is characterized by hypogonadism and is the **most common sex chromosome abnormality in females.**

Karyotypic Abnormalities

- **Missing of an entire X chromosome:** This resulting in a 45, X karyotype due to *nondisjunction* of X chromosomes during meiosis. Genetic constitution hence becomes 45 XO.
- **Structural abnormalities of the X chromosomes:** These includes isochromosome of the long arm, translocations, ring chromosome, and deletions (Xp/Xq).
- **Mosaics:** The mosaic patients have combination of a 45, X cell population along with one or more karyotypically normal or abnormal cell types. *Examples:* (1) 45, X/46, XX; (2) 45, X/46, XY. It is known as mosaic Turner syndrome.



Small stature
Low posterior hairline
Webbing of neck
Coarctation of aorta
Poor breast development and widely spaced nipples
Cubitus valgus
Streak ovaries, infertility, amenorrhea
Multiple pigmented nevi
Short 2nd and 3rd metacarpals
Peripheral lymphedema at birth

FIG. 23.4: Clinical features of Turner syndrome.

Clinical Features (Fig. 23.4)

Turner syndrome is usually not discovered before puberty. It presents with **failure to develop normal secondary sex characteristics**. Important diagnostic features are:

- **Adult women** with **short stature** (<5 feet tall) **primary amenorrhea and sterility**. Raised FSH levels are noted.
- *Other features are:*
  - **Webbed neck,** and **low posterior hairline,** wide/increased carrying angle at the elbows (**cubitus valgus**), **Madelung deformity** of the forearm and wrist, broad chest (**shield chest**) with widely spaced nipples and hyperconvex fingernails.
  - The **genitalia remains infantile, breast development is inadequate,** and there is little pubic hair. The ovaries are converted to fibrous streaks. Lack of secondary sexual characteristics.
  - Pigmented nevi and pilomatricoma as the age advances.
  - Congenital lymphedema, short fourth metacarpals and/or metatarsals, horseshoe kidney, osteoporosis.
  - **Cardiovascular anomalies** such as congenital heart disease particularly **coarctation of the aorta** or **bicuspid aortic valve** may be present. Aortic dissection or rupture is a common cause of death. Systemic hypertension is seen in 30% of cases. No mental retardation.

INTELLECTUAL DISABILITY

Q. PS15.1 Describe the etiology of mental retardation.

Definition: It is a neurodevelopmental disorder that begins in childhood and is characterized by limitations in both intelligence and adaptive skills, affecting at least one of three adaptive domains (conceptual, social, and practical), with varying severity. Earlier was termed as mental retardation.

Causes of Intellectual Disability

See **Box 23.4**.

Assessment of Degree of Intellectual disability

- **Adaptive function:** Impaired functioning in at least **one** of the following three domains, affecting participation in multiple everyday settings: conceptual domain, social domain, and practical domain. The American Psychiatric Association's DSM-5 categorizes adaptive impairment from mild to profound.
- **Intellectual function:** It is assessed by IQ testing **(Table 23.1).**

$$\text{IQ} = \frac{\text{Mental age}}{\text{Chronological age}}$$

INHERITANCE

Inheritance patterns are classified as either monogenic (Mendelian and non-Mendelian) or polygenic.

Box 23.4: Causes of intellectual disability.

- Genetic and chromosomal disorders, e.g., Down syndrome and fragile X syndrome
- *CNS lesions:*
  - Hydrocephalus
  - Microcephaly
  - Cerebral palsy
  - Post-traumatic, postmeningitic and postencephalitic states
  - Birth trauma, kernicterus
- *Environmental causes:*
  - *Associated intrauterine infections:* Congenital infections, congenital rubella syndrome, cytomegalovirus, and other viruses
  - *Intrauterine exposure to toxins and other insults:* Alcohol, hypoxia or malnutrition
  - *Postnatal causes:* Exposure to toxins, infection, and heavy metals
- Metabolic disease, e.g., cretinism, phenylketonuria, mucopolysaccharides, inborn errors of metabolism (e.g., glycogen storage diseases)

Single-Gene or Monogenic Disorders/Mendelian Disorders

Genetic disorders that result from mutations in single gene are called as single-gene or monogenic (Mendelian) disorders. This type of inheritance is called *Mendelian inheritance.*

TABLE 23.1: Intellectual disability by IQ range.

Severity of mental retardation	*IQ range*
Mild	50–55 to 70
Moderate	35–40 to 50–55
Severe	20–25 to 35–40
Profound	Below 20–25

Polygenic

Examples: Hypertension, diabetes—caused by the cumulative and interactive effects of genetic variation in more than one gene.

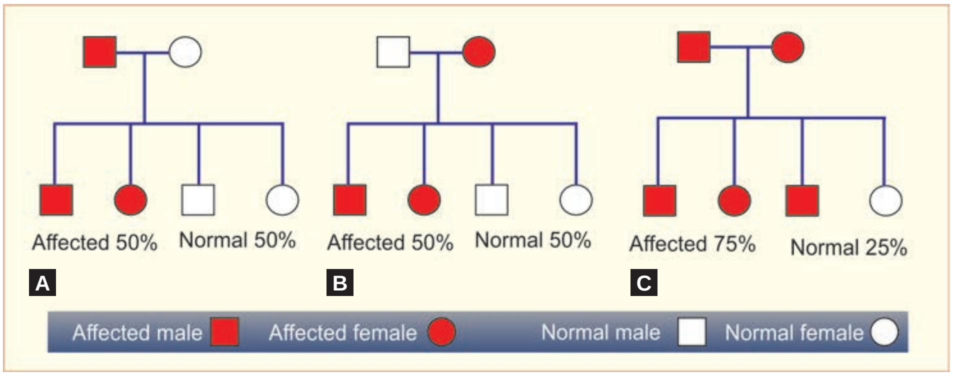
Q. List the characteristics of autosomal dominant inheritance with examples. What do you mean by penetrance and variable expressivity?

Autosomal Dominant Pattern of Inheritance

- It is determined by the presence of one abnormal gene on one of the autosomes (chromosomes 1–22)
- Disease is in **heterozygotes** (These disorders generally manifest when one of the two homologous (paired) chromosomes carries a mutant gene).

The general characteristics of autosomal dominant inheritance:

- **Location of mutant gene:** These are found on **autosomes**.
- **Required number of defective genes:** Only **one copy of the mutant** (abnormal) **gene** is required for effects.
- The disorder is **transmitted in a vertical (parent to child) pattern, appearing in multiple generations**.
- **Sex affected:** Males and females are equally affected.
- **Pattern of inheritance: Every affected individual has one affected parent**.
- Unaffected individuals (family members who do not manifest the trait) do not pass the disorder to their children.
- **Risks of transmission (Figs. 23.5A to C) to children (offspring):** Affected males and females have an equal risk of passing on the disorder to children.



FIGS. 23.5A TO C: Pedigree illustrating autosomal dominant transmission. (A and B) One parent is affected; (C) Both parents are affected. Note that both males and females are affected equally.

TABLE 23.2: Examples of autosomal dominant and autosomal recessive disorders.

System	*Autosomal dominant disorder*	*Autosomal recessive disorder*
Nervous	➢ Huntington disease Neurofibromatosis ➢ Tuberous sclerosis ➢ Myotonic dystrophy	➢ Friedreich's ataxia ➢ Spinal muscular atrophy ➢ Ataxia telangiectasia
Skeletal/ Dermatological	➢ Marfan syndrome ➢ Achondroplasia ➢ Osteogenesis imperfecta ➢ Noonan syndrome	➢ Alkaptonuria ➢ Ehlers-Danlos syndrome ➢ Albinism
Metabolic	➢ Familial hypercholesterolemia ➢ Intermittent porphyria	➢ Cystic fibrosis ➢ Phenylketonuria ➢ Lysosomal storage diseases ➢ Galactosemia ➢ Hemochromatosis ➢ Glycogen storage diseases ➢ Alkaptonuria
Hematopoietic	➢ Hereditary spherocytosis ➢ Von Willebrand disease	➢ Sickle cell anemia ➢ Thalassemia ➢ Homocystinuria
Renal	Polycystic kidney disease	➢ Congenital adrenal hyperplasia
Gastrointestinal	Familial polyposis coli	➢ Wilson's disease ➢ Dubin-Johnson syndrome
Pulmonary		➢ Alpha-1 antitrypsin deficiency ➢ Cystic fibrosis

  - ***When only one parent is affected and other is normal:*** An affected individual has a 50% (1 in 2) chance of passing on the deleterious genes for *each* pregnancy, and therefore of having a child affected by the disorder. This is called as the **recurrence risk** for the disorder.
  - ***When both parents are affected:*** It has 75% chance of children being affected and a 25% chance to be normal.
- Finding of **male-to-male transmission** essentially confirms autosomal dominant inheritance.

  Examples of autosomal dominant and autosomal recessive disorders are listed in **Table 23.2**.
- **Additional properties:**
  - **Penetrance:** Penetrance is the percentage of individuals with the mutation who present with clinical symptoms.
    - **With complete penetrance,** all individuals show clinical symptoms.
    - **With incomplete penetrance** or **reduced penetrance,** only some individuals show disease and in **nonpenetrance** (gene is not expressed at all) individuals may not show any symptoms.
    - For example, *retinoblastoma:* AD malignant eye tumor is a good example of reduced penetrance. About 10% of the obligate carriers of the RB susceptibility gene (affected parent and affected child or children) do not have the disease.
  - **Variable expressivity:** It refers to variations in expression (qualitatively or quantitatively) of severity of the same disorder among individuals (even within the same family), who have the abnormal gene. In some, the disorder may be mild and in others it may show significant symptoms. Penetrance may be complete, but severity of disease can vary greatly. Well-studied example is **neurofibromatosis type 1, or von Recklinghausen disease**.

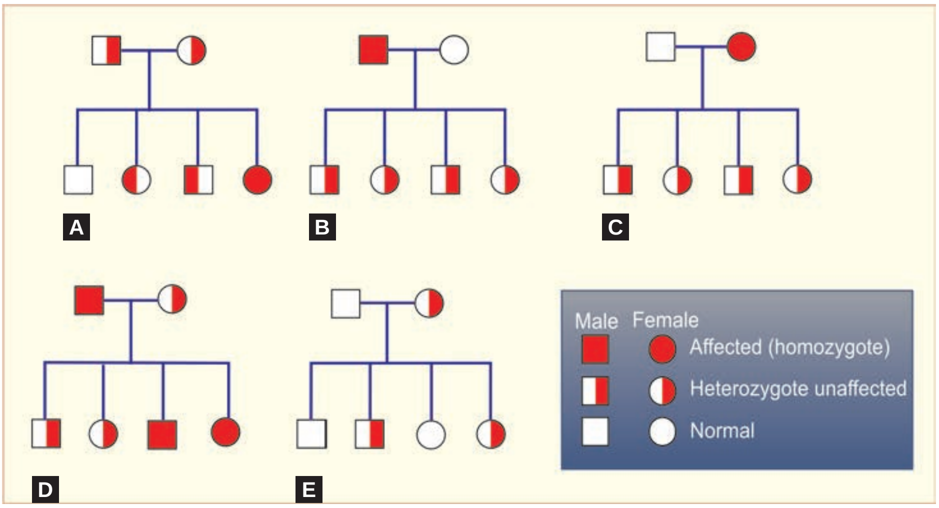
Q. Discuss autosomal recessive inheritance with examples.

Autosomal Recessive Pattern of Inheritance

- Autosomal recessive inheritance involves mutations in both copies of a gene.
- These disorders generally manifest when both the homologous chromosomes carry mutant genes **(homozygous** state).

The general features of these disorders are:

- **Location of mutant gene:** These genes are located on **autosomes**.
- **Required number of defective gene:** Symptoms of the disease appear only when an individual has **two copies** of the mutant gene. The heterozygote state is called as a carrier. In the carrier state, the product of the normal gene is able to compensate for the mutant allele and is hence the patients are asymptomatic.
- **Horizontal transmission:** The observation of multiple affected members of kindred in the same generation, but no affected family members in other generations.
- **Pattern of inheritance:** For a child to be at risk, both parents must be having at least one copy of the mutant gene. *Almost all inborn errors of metabolism are autosomal recessive disorders.*
- **Sex affected:** Males and females being equally affected, though some traits exhibit different expression in males and females (ovarian cancer, hypospadias).
- **Consanguineous marriage:** It is common predisposing factor.
- Recurrence risk of 25% for parents with a previous affected child.
- **Risks of transmission (Figs. 23.6A to E) to children (offspring):**
  - ***When both parents are heterozygous for the condition:*** Heterozygous parents carry one mutated gene and normal gene. When two ***heterozygotes*** mate, 25% of the children will be affected, 50% will be unaffected heterozygotes and 25% will be normal.



FIGS. 23.6A TO E: Pedigree illustrating mechanism of autosomal recessive transmission. (A) Both parents are unaffected heterozygotes; (B and C) One parent is sufferer (homozygous) and other is normal; (D) One parent is sufferer and other is unaffected heterozygote; (E) One parent is normal and other is an unaffected heterozygote.

  - ***When one parent is affected and the other is normal:*** All the children will be unaffected heterozygote.
  - ***When one parent is affected and the other is heterozygote:*** The chances are that 50% of children will be unaffected heterozygote and 50% homozygous affected.
  - ***When one parent is normal and the other is heterozygote:*** This may result in 50% unaffected heterozygote carriers and 50% normal children.
- If the frequency of an autosomal recessive disease is known, then frequency of the heterozygote or carrier state can be calculated from the *Hardy-Weinberg formula:* **p2 + 2pq + q2 = 1,** where p is the frequency of one of a pair of alleles and q is the frequency of the other.

  Examples of autosomal dominant and autosomal recessive disorders are listed in **Table 23.2**.

X-Linked Pattern of Inheritance

Q. Discuss X-linked inheritance with examples.

Almost all sex-linked Mendelian disorders are X-linked. Males with mutations affecting the Y-linked genes are usually infertile.

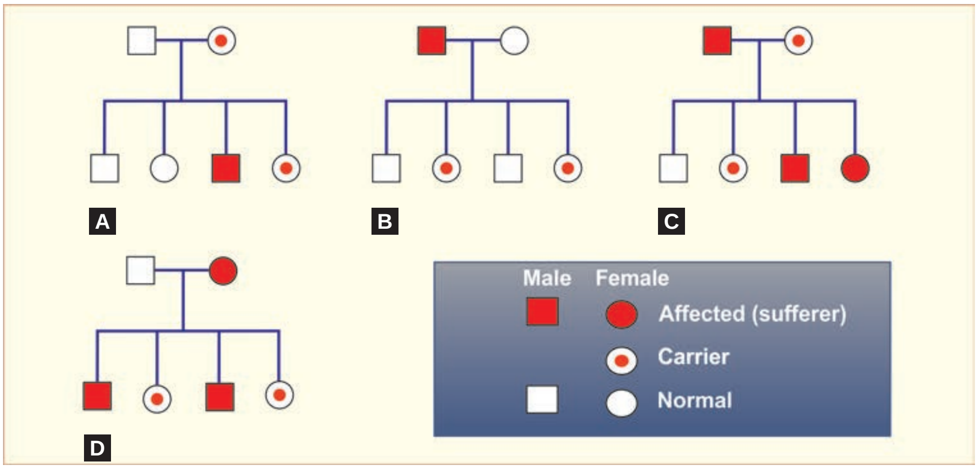
Expression of an X-linked disorder is different in males and females. Though X-linked disorders may be inherited either as dominant or recessive, almost all X-linked disorders have recessive pattern of inheritance.

Characteristics of X-linked inheritance:

- Males are more commonly and more severely affected than females.
- **Female carriers** are generally unaffected, or if affected, they are affected more mildly than males.
- Affected males will have only carrier daughters.
- Carrier women have a 25% risk for having an affected son, a 25% risk for a carrier daughter, and a 50% chance for a child that does not inherit the mutated X-linked gene.

X-linked Recessive Traits

- **Location of mutant gene:** Mutant gene is on the X chromosome and there is no male-to-male transmission.
- **Required number of defective gene:** One copy of mutant gene is required for the manifestation of disease in males, but two copies of the mutant gene are needed in females.
- **Sex affected:** Males are more frequently affected and manifest disease than females; daughters of affected male are all asymptomatic carriers. In many diseases, males do not survive.
- **Pattern of inheritance (Figs. 23.7A to D):** Transmission is through female carrier (heterozygous). Mothers are always carriers and all their sons are affected. The disease is never passed from father to son.
- Very rarely, a female can develop the disease due to:
  - Female having Turner syndrome (XO) with only one X chromosome.
  - Presence of testicular feminization syndrome.



FIGS. 23.7A TO D: Mode of X-linked recessive transmission. Note the absence of male-to-male transmission. (A) Male is normal and female is a carrier; (B) Male is sufferer and female is normal; (C) Male is a sufferer and female is a carrier; (D) Male is normal and female is a sufferer.

  - Father with mutation in X chromosome and a carrier female.
  - Affected father and carrier mother.
  - Inactivation of normal X chromosome in most cells (Lyon hypothesis).

Examples of X-linked recessive disorders are shown in **Table 23.3**.

TABLE 23.3: Examples of X-linked recessive disorders.

System	*Related X-linked recessive disease*
Musculoskeletal	➢ Duchenne muscular dystrophy ➢ Beckers muscular dystrophy
Blood	➢ Hemophilia A and B ➢ Glucose-6-phosphate dehydrogenase deficiency ➢ Wiskott-Aldrich syndrome
Immune	➢ Agammaglobulinemia
Metabolic	➢ Diabetes insipidus ➢ Hunter disease ➢ Lesch-Nyhan syndrome
Nervous	➢ Fragile-X syndrome ➢ Retinitis pigmentosa ➢ Color blindness

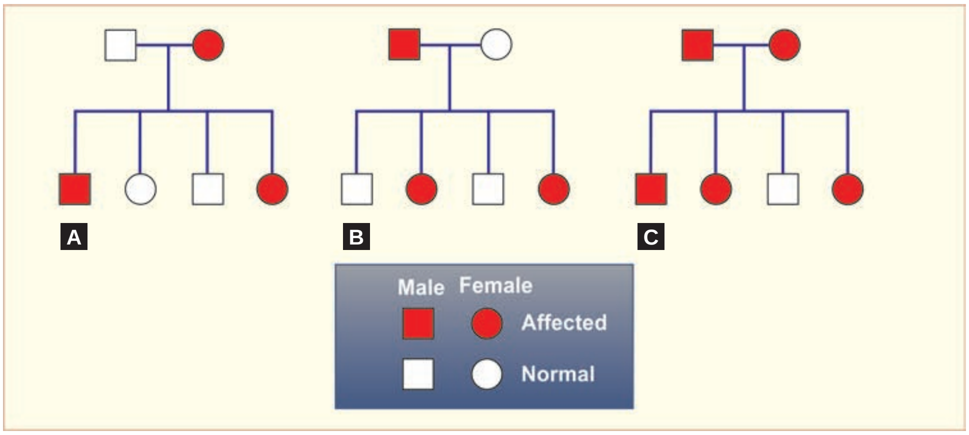
X-linked Dominant Conditions

- Disorders are relatively uncommon (very rare). For example, vitamin D resistance rickets, Alport's syndrome, Rett syndrome
- **Location of mutant gene:** It is located on the X chromosome and there is no transmission from affected male to son. This is because the son's "normal" X chromosome is from mother.
- **Required number of defective gene:** One copy of mutant gene is required for its effect.
  - Often lethal in males and so may be transmitted only in the female line.
  - Often lethal in affected males and they have affected mothers.
  - There is no carrier state as the disease will manifest, even if single chromosome has abnormal gene.
  - These are more frequent in females than in males.
- **Risks of transmission to children (offspring) (Figs. 23.8A to C):**
  - ***When female is affected and the male is normal:*** They transmit the disorder to 50% of their sons and 50% of their daughters.
  - ***When male is affected and the female is normal:*** They transmit to all their daughters but none to their sons. All daughters of an affected father develop disease because the daughter gets abnormal X from the father.
  - ***When both male and female are affected:*** All the females will be affected and half of males will be affected.

Y-linked Diseases

Characterized by:

- Only males are affected.
- An affected male transmits the disorder to all his sons but not to his daughters.
- Most Y-linked genes are related to male sex determination and reproduction, and are associated with infertility. Therefore, it is rare to see familial transmission of a Y-linked disorder.
- For example, Leri-Weill dyschondrosteosis, Langer mesomelic dwarfism, hairy ears.



FIGS. 23.8A TO C: X-linked dominant transmission. Only females are affected. Usually males who inherit the mutant allele die in utero. (A) Normal male and female affected (sufferer); (B) Affected male and normal female; (C) Both male and female are affected.

Digenic Inheritance

- Digenic inheritance explains the occurrence of **retinitis pigmentosa** (RP) in children of parents who each carry a different RP-associated gene.
- Both parents have normal vision, but the offspring who were **double heterozygotes** developed RP.
- Digenic pedigrees exhibit characteristics of both autosomal dominant (vertical transmission) and autosomal recessive inheritance (1 in 4 recurrence risk).
- Other disorders with digenic inheritance—Bardet-Biedl syndrome, Hirschsprung disease, Long QT syndrome.

Mitochondrial Inheritance

- An individual's mitochondrial genome is entirely derived from the mother.
- Examples include Leber optic atrophy, **MELAS** (myopathy, encephalopathy, lactic acidosis, and stroke-like episodes), **MERRF** (myoclonic epilepsy associated with ragged red fibers), and **Kearns-Sayre syndrome** (ophthalmoplegia, pigmentary retinopathy, and cardiomyopathy).

Pseudodominant Inheritance

Pseudodominant inheritance of a recessive trait in two generations of a family without consanguinity mimics a dominant pattern. Pseudodominant inheritance of hereditary hemochromatosis (HH), an autosomal recessive disorder, can be attributed to the high carrier frequency of HFE alleles in individuals of European descent. In this case, the father is homozygous for the mutated alleles and the mother is the carrier of the genetic mutation; therefore, there are 50% chances that the offspring will inherit mutated genes from both the parents and will have hemochromatosis.

Triplet Repeat Expansion Disorders

- Caused by expansion in the number of three-base-pair repeats.
- An error in replication can result in expansion of that number, referred to as **premutation**.
- There is a clinical correlation to the size of the expansion, with a greater expansion causing more severe and/or earlier age of onset for the disease. The observation of increasing severity of disease and early age of onset in subsequent generations is termed **genetic anticipation** and is a defining characteristic of triplet repeat expansion disorders.

  Examples of triplet repeat expansion disorders are listed in **Table 23.4**.

TABLE 23.4: Examples of triplet repeat expansion disorders.

Disease	*Triplet repeated*	*Disease*	*Triplet repeated*
Huntington	CAG	Fragile X syndrome (FRAXA)	CGG
Myotonic dystrophy	CTG	FXTAS (Fragile X-associated tremor/ ataxia syndrome)	CGG
X-linked spinal and bulbar muscular atrophy	CAG	Machado-Joseph disease (MJD)	CAG
Spinocerebellar ataxia type I	CAG	Friedreich's ataxia	GAA

Simple Tandem Repeat Mutation

- Variations in the length of simple tandem repeats of DNA are thought to arise as the result of slippage of DNA during meiosis and are termed microsatellite (small) or minisatellite (larger) repeats.
- These repeats are unstable and can expand or contract in different generations. This instability is related to the size of the original repeat, in that longer repeats tend to be more unstable.
- For example, Huntington disease, sickle cell anemia, Machado-Joseph disease, Fragile X, myotonic dystrophy.

Genetic Imprinting

- The two copies of most genes are functionally equivalent. In a small number, only one of the pair is transcribed.
- The active gene will be that inherited from a specific parent, and the other copy is silenced associated with methylation of DNA (**epigenetic modification** of a gene not due to a DNA mutation).

Conditions Associated with Genetic Imprinting

- **Prader-Willi syndrome** with paternal chromosome deletion.
- **Angelman syndrome** with maternal chromosome deletion.
- **Uniparental disomy (UPD):** Rare occurrence of a child inheriting both copies of a chromosome from the same parent is another genetic mechanism that can cause Prader-Willi and Angelman syndromes.
- Other conditions associated with imprinting are Beckwith-Wiedemann syndrome and Russell-Silver syndrome, Duchenne muscular dystrophy (DMD) in females and epigenetic silencing in oncogenesis, e.g., colon cancer 3p21 MLH1.

Pleiotropy

- Genes that exert effects on multiple aspects of physiology or anatomy are pleiotropic.
- *For example:* Marfan syndrome (affects eye, the skeleton, and the cardiovascular system), cystic fibrosis (affects sweat glands, lungs, pancreas, and genitourinary system), osteogenesis imperfecta (affects bones, teeth, and sclera), sickle cell anemia (affects RBCs, bone, and spleen).

Locus Heterogeneity

- Disease that can be caused by mutations at different loci in different families is said to exhibit locus heterogeneity.
- *Osteogenesis imperfecta (OI):* Subunits of procollagen triple helix are encoded by two genes, one on chromosome 17 and the other on chromosome 7. Mutation in either of these genes can alter the structure of the collagen molecules and lead to OI, disease states are often indistinguishable.

Polymorphisms

- A polymorphism is defined as one that exists with a population frequency of >1%.
- Most common polymorphisms are neutral but some cause subtle changes in gene expression or in protein structure and function. For example, cystic fibrosis, hemochromatosis, alpha-1 antitrypsin deficiency, spinomuscular dystrophy.

GENE THERAPY

Q. Write short note on gene therapy.

Definition: Gene therapy is the insertion of genes into an individual's cells and tissues to treat a disease, such as a hereditary disease in which a deleterious mutant allele is replaced with a functional one.

To be effective, the gene therapy requires methods that ensure the safe, efficient and stable introduction of genes into human cells. Gene therapy uses genes to treat or prevent disease. First done on September 14, 1990 for Ashanthi DeSilva suffering from severe combined immunodeficiency (SCID) where the missing gene introduced through processed WBC.

Approaches for Correcting Faulty Genes

- A normal gene may be inserted into a nonspecific location to replace a nonfunctional gene.
- An abnormal gene could be swapped through homologous recombination.
- Repair through selective reverse mutation.
- The regulation of a particular gene could be altered.

Types of Gene Therapy

The cells in the body can be divided into two main categories: (1) somatic cells and (2) germ cells.

1. **Somatic cell therapy:** It involves delivering a correcting gene to somatic cells in the affected tissues. Somatic cells are the nonreproductive cells and its therapeutic effect ends with the individual receiving it and is not passed on to the future generations. Hence, somatic cell therapy is considered as a safer approach. This type of gene therapy is used for disorders such as cystic fibrosis, muscular dystrophy, cancers, and certain infectious diseases.
2. **Germ cell therapy:** In germ cell therapy, germ cells (egg or sperms) are used and it results in permanent changes that are passed on to the future generations. Thus, it offers the possibility of permanently eliminating some diseases from a particular family and ultimately from the population. It is not accepted at present due to ethical reasons.

Arguments for Germline Gene Therapy

- **Medical utility:** The potential of a true "cure".
- **Medical necessity:** May be only way to cure some diseases.
- **Prophylactic efficacy:** Better to prevent a disease rather than to treat pathology.
- **Parental autonomy:** Parents can make choices about what is best for their children.
- Easier, more effective than somatic gene therapy.
- Eradication of disease in future generations.
- **Part of being human:** Supporting human improvement.

Forms of Gene Therapy

There are two basic forms of somatic gene therapy: (1) *ex vivo* and (2) *in vivo*.

1. ***Ex vivo:*** Transfer of gene in cultured cells and finally these cultured cells are reintroduced into patients.
2. ***In vivo:*** Delivery of genes into cells of particular tissues. The gene may be transferred by a viral vector or by a nonviral method. This is most often used technique.

Vectors in Gene Therapy

The most common form of gene therapy involves insertion of normal gene into the genome with the help of certain carriers called **vectors**. These vectors can be divided into two main types: (1) viral and (2) nonviral vectors.

Viral vectors: The various viruses include retroviruses, adenoviruses, adeno-associated viruses, and herpes simplex viruses.

Nonviral methods: Gene delivery can also be carried by nonviral methods. These have some advantages. They do not elicit an immune response, safer and simpler to use and allow large-scale production. The nonviral methods include: direct inoculation/naked DNA, liposomal-mediated DNA transfer, gene gun method, and dendrimers. Pure DNA constructs and lipoplexes are used for in vivo transfer while bone marrow cells are used for ex vivo transfer.

Problems/Limitations of Gene Therapy

- **Short-lived nature of gene therapy**. Hence, patients will have to undergo multiple rounds of gene therapy.
- **Immunotoxicity:** Gene therapy may stimulate the immune response against introduced gene and reduce the effectiveness of gene therapy.
- **Problems with viral vectors:** Viral vectors may sometimes cause potential problems to the patient like: toxicity and inflammatory responses. In addition, the viral vector, once inside the patient, may recover its ability to cause disease.
- **Gene silencing**—repression of promoter.
- **Multifactorial disorders:** Genetic disorders due to single gene mutations usually show best response to gene therapy. Unfortunately, some the most commonly occurring disorders (e.g., atherosclerosis, hypertension, diabetes, Alzheimer's disease, and rheumatoid arthritis) are multifactorial and are difficult to treat effectively using gene therapy.
- **Phenotoxicity**—complications arising from overexpression or ectopic expression of the transgene
- **Risk of inducing a tumor (insertional mutagenesis):** If the gene is integrated in the wrong place in the genome (e.g., in a tumor suppressor gene), it could induce a tumor.
- **Risk of death:** Deaths have occurred due to gene therapy.

Therapeutic Applications (Table 23.5)

- Not been approved for clinical use.
- Trials are being conducted on using gene therapy in the treatment of various genetic disorders, cancers, infectious diseases, and other diseases such as Alzheimer's disease and atherosclerosis.

TABLE 23.5: Therapeutic application of gene therapy.

Disease	*Gene therapy trials*
Inherited single gene disorders—to provide a normally functioning gene	
Severe combined immunodeficiency	Adenosine deaminase (ADA)
Cystic fibrosis	Cystic fibrosis transmembrane regulator (CFTR)
Familial hypercholesterolemia	LDL receptor
Emphysema	Alpha-1 antitrypsin
Hemophilia B	Factor IX
Thalassemia	Alpha- or beta-globin
Sickle cell anemia	Beta-globin
Duchenne muscular dystrophy	Dystrophin
Cancer therapy—to augment the immune response/to direct tumor lysis	
Nasopharyngeal cancer	P53
Melanoma	Tumor necrosis factor
Retinoblastoma and mesothelioma	Thymidine kinase (suicide gene therapy)
Antibody delivery—not been used clinically	

HUMAN GENOME PROJECT

Q. Write short note on human genome and human genome project.

Introduction

- **Genome:** A **genome** is the entire DNA in an organism, including its genes. The human genome is estimated to contain 30,000–40,000 genes that are divided among the 23 chromosomes. The 23 different chromosomes, 22 are autosomes (numbered 1–22) and 1 pair of sex chromosomes (X and Y). The functions of over 50% of discovered genes are not known.
- **Gene mapping:** It is the process of identifying and sequencing each and every human gene of the human genome. The map of the human genome provides a picture of locations, and structures of genes.
- **Genetic mapping** (linkage analysis): A genetic map describes the order of genes and defines the position of a gene relative to other loci on the same chromosome.
- **Physical mapping:** Physical mapping indicates the position of genes in a chromosome, which is determined by physical distances (measured in base pairs) between genes.

Organisms and their genomic size are presented in **Table 23.6.**

TABLE 23.6: Organisms and their genomic size.

Organism	*Genomic size in base pairs*
Epstein-Barr virus	0.172×10^6
Bacteria *(E. coli)*	4.6×10^6
Yeast	12.1×10^6
Nematode worm *(C. elegans)*	95.5×10^6
Fruit fly	180×10^6
Human	3200×10^6

(E. coli: Escherichia coli; C. elegans: Caenorhabditis elegans)

The **human genome project (HGP)** is an international scientific research project to understand the genomes of humans and other organisms. It was started in 1990 under **Dr James D Watson** at the United States National Institute of Health. In addition to the United States, the international consortium comprised geneticists in the United Kingdom, France, Germany, Japan, China, and India.

Goals of Human Genome Project

- Understand and **identify all genes** of the human genome.
- Determine the **human DNA sequence:** The primary focus of the HGP was to obtain DNA sequence for the entire human genome. The goal was to map all genes of the human genome and also to map human inherited diseases. Thus included creation of genetic maps, development of physical maps, and determination of the complete human DNA sequence.
- **Develop software for large-scale DNA analysis,** store all found information in databases and improve tools for data analysis.
- Transfer-related technologies to the private sector
- **Collect and distribute data**
- **Study the ethical, legal, and social issues** (ELSI) of **genetic research** that may arise from the project.

Components involved in human genome are diagrammatically shown in **Figure 23.9**.

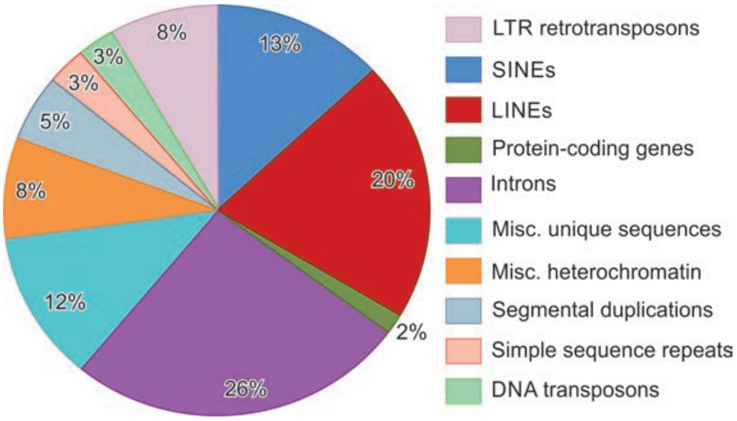


FIG. 23.9: Components of human genome.

All humans have unique gene sequences. Therefore, the data published by the HGP does not represent the exact sequence of each and every individual's genome. It is the combined genome of a small number of anonymous donors. The HGP genome is a scaffold for future work in identifying differences among individuals.

Uses of Human Genome Project

Human genome project will shed light on a wide range of basic questions, to identify the number of genes in humans, how cells work, how living things evolved, how single cells develop into complex creatures, and what exactly happens when we become ill. The understanding of the genome provides clues for:

1. **Etiology** of cancers, Alzheimer's disease, etc.
2. Defining the **pathogenesis** of a disease and to study the disease processes at molecular level.
3. **Susceptibility** of an individual to a variety of illnesses, e.g., carcinoma breast, disorders of hemostasis, liver diseases, cystic fibrosis, etc.
4. Predict new ways **to prevent** a number of diseases that affect the human beings.
5. To **diagnose and treat** disease. Target genes for treatment and management of diseases.
6. *Human development and anthropology:* Analysis of similarities between DNA sequences from different organisms helps to **study evolution**.
7. **Researcher:** By visiting the human genome database on the Worldwide Web, researcher can examine what other scientists have written about the gene.

Ethical Issues (Box 23.5)

Human genome project helps to identify disease-causing genes, thereby can lead to improvements in diagnosis, treatment, and prevention. It is estimated that most individuals harbor several serious recessive genes. However, completion of the human genome sequence and determination of the association of genetic defects with disease has raised many new issues with implications for the individual and mankind.

Box 23.5: Ethical issues in human genome project (HGP).

- Fairness in the use of genetic information
- Privacy and confidentiality
- Psychological impact and stigmatization
- Genetic testing
- Reproductive issues
- Education, standards, and quality control
- Commercialization
- Conceptual and philosophical implications.

GENETIC MUTATIONS

Q. BI7.3 Describe gene mutations and basic mechanism of regulation of gene expression.

Mutations are alterations in the genome of a cell.

Mechanism

- As a result of errors during DNA replication or cell division
- Ineffective DNA repair mechanisms
- Damage to DNA caused by endogenous and exogenous toxins

Types of mutations

- Mutations according to affected cell population
- Chromosomal aberrations
- Gene mutations

A. **Based on the affected cells**
  - Germline mutation (gametic mutation):
    - Mutations in the cells from which egg or sperm cells develop
    - These mutations can, therefore, be passed on to offspring.
  - Somatic mutation:
    - Acquired mutations that are present only in certain somatic cells
    - Primarily affect only one allele of a gene
    - Do not occur in the germline and therefore cannot be passed on to offspring via the ovum or sperm
    - Almost all malignancies are preceded by a somatic mutation.

B. **Chromosomal aberrations**
  - Chromosomal aberrations are mutations affecting large segments of DNA
  - They may be visible on karyogram
  - Numerical chromosomal aberrations or structural chromosomal aberrations (discussed earlier).

Q. Write a short note on gene mutations.

C. **Gene mutations**

Types of gene mutations include:

- Point mutation: alteration of a single DNA base pair, e.g., sickle-cell disease
- Deletion: loss of one or more base pairs, e.g., cystic fibrosis
- Insertion: addition of one or more base pairs, e.g., beta-thalassemia
- Substitution: one or more base pairs are replaced by different base pairs
- Trinucleotide repeat expansion:
  - Increased repetition of base triplets that leads to faulty protein synthesis or folding
  - Examples: Fragile X syndrome, Huntington disease, myotonic dystrophy.

Gene mutations can be classified based on the outcome:

- **Frameshift mutation:**
  - Shift in the reading frame caused by insertion or deletion of a number of nucleotides not divisible by 3, which leads to modified amino acid coding in the gene segments downstream.
  - It results in the synthesis of shorter or longer proteins that have a modified function or are dysfunctional.
  - Examples: Tay-Sachs disease, Duchenne muscular dystrophy.
- **In-frame deletion or insertion:**
  - Deletion or insertion of three, six, nine, or more base pairs (always in triplets!), without a shift in the reading frame, but with deletion or insertion of one, two, three, or more amino acids in the protein during translation.
- **Silent mutation:**
  - Altered codon, which codes for the identical amino acid.
- **Nonsense mutation:**
  - Formation of a stop codon, which leads to alterations in the splicing process and early termination of translation.
- **Missense mutation:**
  - Altered codon, which codes for a different amino acid
  - Example: Sickle cell disease (glutamic acid → valine)
  - Considered as "conservative" missense mutation when the new amino acid is similar in chemical structure to the original amino acid.
- **Splice mutation:**
  - Alterations (especially point mutations) in the nucleotide sequences required for splicing (e.g., on the exon-intron border or at the junction) that lead to defective mRNA and shortened proteins.
  - Examples: Some types of β-thalassemia, dementia, cancers, and epilepsy.
- **Dominant negative mutation:**
  - A gene mutation that results in nonfunctional protein that impairs the function of protein produced by the wild-type allele in heterozygotes.

MISCELLANEOUS

Q. Write short note on proteomics/proteome.

Proteome

- The term proteome is derived from proteins expressed by a genome. It refers to all the proteins produced by an organism and proteins are the functional units. Thus, the proteome represents full sets of proteins produced by the body and is similar to the term genome for the entire set of genes. Human body contains more than 2 million different proteins, each having different functions.
- Proteomics is the study of the proteome (full set/entire library of proteins in a cell type or tissue) and its variation/relationship to disease.
- Amino acids are the basic units of proteins and are very small. Each amino acid consists of atoms ranging from 7 to 24 and cannot be identified under even the powerful microscopes.
- *Uses:* Proteomic technologies play an important role in drug discovery, diagnostics, and molecular medicine. When a defective protein-causing particular diseases are found, new drugs can be developed to either alter the shape of a defective protein or mimic a missing one.

Epigenetics

Q. Write a short note on epigenetics.

Definition: Epigenetics is a **reversible, heritable change/alteration** in gene expression which occurs without mutation and is unrelated to gene nucleotide sequence. Epigenomics is the study of epigenetics. Epigenetic alterations are associated with cancers and other diseases. Unlike genetic changes in cancer, epigenetic changes are reversible.

- In normal cells, the majority of the genome is not expressed. Some portions of the genome are silenced by DNA methylation and histone modifications.
- In some tumors, epigenetic changes may directly contribute to tumor development. Epigenetic changes involve post-translational modifications of histones and DNA methylation, both of which affect gene expression.
- In cancer cells, there is global DNA hypomethylation and selective promoter-localized hypermethylation.

Examples:

1. **Silencing genes by hypermethylation** (epigenetic mechanism)
    a. *Tumor suppressor genes:* Examples: p53 can be indirectly inactivated through silencing ARF by hypermethylation. This hypermethylated ARF prevents inhibition of the MDM2 oncogenic protein and the enhancement of p53 degradation; *BRCA1* in breast cancer and VHL in renal cell carcinomas.
    b. *DNA repair genes:* Mismatch-repair gene *MLH1* in colorectal cancer.
2. **Hypomethylation:** The genome of cancer cells may also undergo global DNA hypomethylation. Gene hypomethylation can cause chromosomal instability, derepression of growth regulatory genes, and overexpression of antiapoptotic genes, which may induce tumors.

Clinical Applications

- Use of epigenetic tumor markers.
- Use of epigenetic therapeutic agents (e.g., azacitidine, decitabine, vorinostat) in the treatment of myelodysplastic syndromes (MDS) and lymphoma.

Pharmacogenomics

Q. Write short note on pharmacogenomics and pharmacogenetics.

- Pharmacogenetics or pharmacogenomics is the study of interaction between genetics and therapeutic drugs.
- Pharmacogenetics is the study of unexpected drug response result and to look for a genetic cause.
- Pharmacogenomics is the study of identifying genetic differences within a population that explain certain observed responses to a drug or susceptibility to a health problem.

Applications

- To develop a drug that has maximum therapeutic effect and produces least damage to adjacent healthy cells.
- To prescribe drugs depending on the patient's genetic profile so as to reduce the adverse reactions.
- To determine the accurate dosage.
- To determine drug responses in the treatment of cardiac, respiratory, and psychiatric conditions.
- To develop targeted therapy (e.g., psychiatry, dementia, cardiac conditions) and in the treatment of breast cancer (testing for HER2 receptor for response to trastuzumab) and other cancers (e.g., testing for BCR-ABL for response to imatinib in CML; testing for epidermal growth factor receptor response to gefitinib and erlotinib in lung cancer).

List of chromosomal disorders are presented in Table 23.7.

TABLE 23.7: List of chromosomal disorders.

Chromosome	*Abnormality*	*Disease association*
X	XO	Turner syndrome
Y	XXY	Klinefelter syndrome
Y	XYY	Double Y syndrome
Y	XXX	Trisomy X syndrome
Y	Xp21 deletion	Duchenne/Becker syndrome congenital adrenal hypoplasia, chronic granulomatus disease
1	1p (somatic) monosomy trisomy	Neuroblastoma

Contd...

Contd...

Chromosome	***Abnormality***	***Disease association***
2	Monosomy trisomy 2q	Growth rerdation, developmental and mental delay, and minor physical abnormalities
3	Monosomy trisomy (somatic)	Non-Hodgkin lymphoma
4	Monosomy trisomy (somatic)	Acute nonlymphocytic leukemia (ANLL)
5	5p deletion	Cri du chat; Lejeune syndrome
5	5q (somatic) monosomy trisomy	Myelodysplastic syndrome
6	Monosomy trisomy (somatic)	Clear-cell sarcoma
7	7q 11.23 deletion	William's syndrome
8	Monosomy trisomy	Myelodysplastic syndrome, Warkany syndrome, chronic myelogenous leukemia
9	Trisomy	Complete trisomy 9 syndrome: mosaic trisomy 9 syndrome
10	Monosomy trisomy (somatic)	Acute lymphoblastic leukemia (ALL) or acute nonlymphocytic leukemias (ANLL)
11	11p-	Aniridia: Wilms tumor
11	Monosomy (somatic) trisomy	Myeloid lineages affected [ANLL, myelodysplastic syndrome (MDS)]
12	Monosomy trisomy (somatic)	Chronic lymphocytic leukemia (CLL), Juvenile granulosa cell tumor (JGCT)
13	13q14 deletion	Retinoblastoma
13	Monosomy trisomy	Patau syndrome
14	Monosomy trisomy (somatic)	Myeloid disorders [myelodysplastic syndromes (MDS), ANLL, atypical CML]
15	15q11-q13 deletion monosomy	Prader-Willi, Angelman syndrome
15	Trisomy (somatic)	Myeloid and lymphoid lineages affected, e.g., MDS, ANLL, ALL, CLL
16	16q13.3 deletion monosomy trisomy (somatic)	Rubinstein-Taybi, papillary renal cell carcinomas (malignant)
17	17p-(somatic)	17p syndrome in myeloid malignancies
17	Monosomy trisomy (somatic)	Renal cortical adenomas
18	Monosomy trisomy	Edwards syndrome
19	Trisomy, deletion	
20	20p-	Trisomy 20p syndrome
20	20q-	MDS, ANLL, polycythemia vera, chronic neutrophilic leukemia
20	Monosomy trisomy (somatic)	Papillary renal cell carcinomas (malignant)
21	Monosomy trisomy	Down syndrome
22	22q11.2 deletion	DiGeorge syndrome, velocardiofacial syndrome, conotruncal anomaly face syndrome, CML-reciprocal translocation 9:22 Opitz G/BBB syndrome, Cayler cardiofacial syndrome
22	Monosomy trisomy	Complete trisomy 22 syndrome

GENETIC TESTING

Indications of genetic testing are listed in Table 23.8.

TABLE 23.8: Indications of genetic testing.

Indications for germ line mutation testing	***Indications for analysis of genetic alteration***
➢ *Perinatal analysis* – >35-year old mother – Previous child with genetic abnormalities – Family history – Mother having a known recessive gene or balanced translocation or X-linked genetic disorders – Triple test abnormal – Fetal abnormalities in USG ➢ *Postnatal analysis* – Multiple congenital anomalies – Unexplained mental retardation – Suspected aneuploidy/unbalanced autosome/sex chromosomal abnormality – Multiple spontaneous abortions	➢ *Diagnosis and management of cancer* – Identifying tumor suppressor gene or identifying cytogenetic alteration – Identifying clonal proliferation confirming neoplasm – Identification of mutations that can alter direct therapeutic choices – Determination of therapeutic efficacy ➢ *Diagnosis and management of infectious disease* – Microorganism-specific genetic material to identify and diagnose genetic material – Identification of genetic changes associated with drug resistance – Determination of treatment efficacy

Genome-wide Association Study

- Genome-wide association studies (GWASs) test hundreds of thousands of genes simultaneously and are used in genetics research to associate specific genetic variations with particular diseases.
- It involves scanning the genomes from many different people and looking for genetic markers that can be used to predict the presence of a disease.

POLYMERASE CHAIN REACTION AND ITS APPLICATIONS

Q. Write short essay/note on polymerase chain reaction (PCR).

Kary Mullis discovered polymerase chain reaction in 1983. PCR is a method employed to amplify minute amount of DNA within a few hours. This technique consists of selective amplification of specific target nucleic acid sequences from total DNA by using primers specific for the target region to be amplified.

Basic Steps

- **Denaturation:** In this step, the double-stranded template DNA is denatured by heat (temperature of around 92–96°C) into single-stranded DNA.
- **Annealing:** DNA primers of interest are added along with the four basic deoxynucleotides and the solution is cooled. It causes binding of DNA probes to their specific target regions of the single-stranded DNA at a temperature of around 50–65°C.
- **Extension:** The primers are extended at a temperature of around 68–78°C in the presence of DNA polymerase, dNTPs and Mg^{2+} ions. The newly synthesized DNA strand acts as a template for the next cycle. This cycle is repeated several times (around 25–30 times) and produces millions of copies of the original specific target DNA. To retain the activity of DNA polymerase enzyme at such high denaturation temperature, *Taq* DNA polymerase, extracted from a microorganism *(Thermus aquaticus)* is used in the PCR reaction.

Applications of Polymerase Chain Reaction

Polymerase chain reaction is the starting test used in most of the molecular genetic tests.

- **Diagnosis of hereditary/genetic diseases:** In genetic disorders, genetic mutations can be detected by PCR alone (e.g., Huntington disease), PCR followed by digestion with restriction endonucleases (e.g., diagnosis of spinal muscular atrophy), PCR followed by dot-blot hybridization (e.g., thalassemia mutation detection), PCR followed by capillary electrophoresis for genotyping (e.g., detection of triplet repeat disorders).
- **Sequencing:** It is used as first step for DNA amplification for all methods of DNA sequencing.
- **Detection of pathogens:** To detect small quantities of pathogen DNA (e.g., PCR for *Mycobacterium tuberculosis),* to detect viruses, (including use of reverse transcriptase enzyme for RNA viruses), and real-time PCR (RT-PCR) for quantification of viral load, e.g., hepatitis B and C, human immunodeficiency virus (HIV).
- **Forensic genetics:** To identify DNA sequences that are unique to each individual.

Reverse transcriptase PCR (RT-PCR): Initial step is to convert RNA to complementary DNA and rest of the process is same as PCR. It is used to quantify the amount/number of copies of input DNA/RNA.

Real-time PCR: This technique, quantifies the PCR product in "real-time". It is used to quantify the amount/number of copies of input DNA/RNA.

Immunoblot (Western Blot)

It is a test to detect antibodies. According to molecular weight, the microbial proteins are separated by polyacrylamide gel electrophoresis (PAGE). They are transferred (blotted) on to a nitrocellulose membrane, which is incubated with serum of patient. Binding of specific antibody is detected with an enzyme—anti-immunoglobulin conjugate (similar to in ELISA), and specificity is confirmed by its location on the membrane. The test is a highly specific and can be used to confirm the results of less specific tests such as ELISA.

Lysosomal Storage Disorders

Classification of Lysosomal Storage Disorders

The classification of lysosomal storage disorders has been shown in **Table 23.9**.

TABLE 23.9: Classification of lysosomal storage disorders.

Disorder	*Underlying defect*
Mucopolysaccharidoses	Defective metabolism of glycosaminoglycans
Sphingolipidoses and sulfatidoses	Defective degradation of sphingolipids and their components
Glycogen storage diseases	Defective degradation of glycogen
Oligosaccharidoses	Defective degradation of the glycan portion of glycoproteins
Mucolipidoses	Defective degradation of acid mucopolysaccharides, sphingolipids and/or glycolipids

TABLE 23.10: Various types of mucopolysaccharidoses (MPSs).

Type of disorder	*Enzyme deficiency*
MPS I (Hurler syndrome, Hurler-Scheie syndrome, Scheie syndrome)	α-L-iduronidase
MPS II (Hunter syndrome)	Iduronate-2-sulfatase
MPS III (Sanfilippo disease) ➢ Type A ➢ Type B ➢ Type C	 Heparan *N*-sulfatase α-*N*-acetylglucosaminidase α-glucosaminide N-acetyltransferase
MPS IV (Morquio disease) ➢ Type A ➢ Type B	 Acetylgalactosamine-6-sulfatase β-galactosidase
MPS VI (Maroteaux-Lamy disease)	Arylsulfatase B
MPS VII (Sly disease)	β-glucuronidase

Mucopolysaccharidoses

The various types of mucopolysaccharidoses have been shown in **Table 23.10**.

MPS I (Hurler Syndrome)

- **Head/face:** Prominence of the forehead, broad nose with a flattened nasal bridge, enlargement and protrusion of the tongue, chronic hearing loss, corneal clouding, retinal degeneration or glaucoma; tonsillar/adenoidal hypertrophy (predispose the child to URI), sleep apnea.
- **Heart:** Cardiomyopathy with asymmetric hypertrophy of the ventricular septum, thickening of the aortic and mitral valves, which progress to valvular insufficiency.
- **Abdomen:** Hepatosplenomegaly results in a protuberant abdomen.
- **Neurological:** Mental retardation.

MPS II (Hunter Syndrome)

- Initial symptoms starts at 2–4 years of age with progressive growth delays, resulting in short stature.
- **Head/face:** Macrocephaly, delayed tooth eruption, progressive hearing loss, thickening of the lips, tongue, and nostrils.
- **Heart:** Thickening of the heart valves leading to a decline in cardiac function.
- **Lungs:** Obstructive airway disease.
- **Abdomen:** Hepatosplenomegaly.
- **Skeletal:** Short neck and broad chest, joint stiffness, with restriction of movements.
- **Neurological:** Hydrocephalus, mental retardation, and seizures.

MPS IV (Morquio Syndrome)

- Widely spaced teeth, corneal clouding **(Fig. 23.10A)**, hearing loss, enlarged heart.
- **Abnormal skeletal development:** Scoliosis, hypermobile joints, large fingers, knock-knees **(Fig. 23.10B)**, short trunk with pectus carinatum, bell-shaped chest (ribs flared), severe growth retardation (82–115 cm), odontoid hypoplasia, compression of spinal cord (cervical myelopathy), and dwarfism.

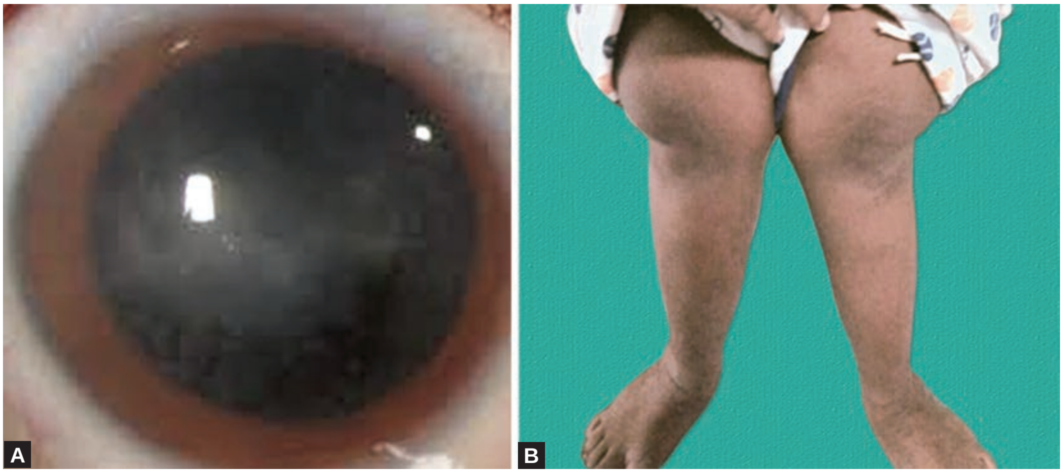
Phenylketonuria (PKU)

- Autosomal recessive disease, due to deficiency of enzyme *phenylalanine hydroxylase* causing failure to convert phenylalanine to tyrosine.
- Developmental delay, mental retardation, seizures, eczema, blue eyes, hyperactivity, aggressive behavior, blond hair and musty/mousy odor.

Galactosemia

Autosomal recessive disease due to deficiency of the enzyme *galactose-1-phosphate uridyltransferase.* It is due to ingestion of galactose (lactose).

- Liver failure (hypoglycemia, bilirubinemia), hepatosplenomegaly
- Renal tubular disorder (acidosis, glycosuria, albuminuria)
- Lethargy, feeding intolerance, failure to thrive, cataracts
- Learning disorders in older children—mental retardation
- About 25% will develop sepsis (*E. coli)* in first 1–2 weeks, if untreated → death.



FIGS. 23.10A AND B: (A) Corneal clouding seen in Hurler and Morquio syndrome; (B) Knock knees in Morquio syndrome.

DIGEORGE SYNDROME

Q. Write a short note on DiGeorge syndrome.

DiGeorge syndrome (DGS) is a constellation of signs and symptoms associated with defective development of the pharyngeal pouch system. Most cases are caused by a **heterozygous chromosomal deletion at 22q11.2**. Chromosome 22q11.2 deletion syndrome (22qDS) includes DGS and other similar syndromes, such as velocardiofacial syndrome.

The classic triad of features of DGS on presentation is **conotruncal cardiac anomalies, hypoplastic thymus, and hypocalcemia (resulting from parathyroid hypoplasia)**.

Cardiac anomalies

- Interrupted aortic arch
- Truncus arteriosus
- Tetralogy of Fallot
- Atrial or ventricular septal defects

Hypocalcemia: Hypocalcemia, resulting from underdevelopment of the parathyroid glands and may present with jitteriness, tetany, or seizures, with low serum calcium, elevated serum phosphorus, and very low parathyroid hormone levels.

Hypoplastic/aplastic thymus: The thymus is absent in patients with complete DGS. In patients with partial DGS, the thymus is present, although it is often reported as hypoplastic.

Immunodeficiency: Immunodeficiency is common in patients with DGS and can range from recurrent sinopulmonary infections (termed partial DGS) to SCID.

GENETIC COUNSELING

Q. AN75.5 Describe the principles of genetic counseling.

Genetic counseling is the process of helping people understand and adapt to the medical, psychological, and familial implications of genetic contributions to disease. This process integrates:

- Collection of a detailed family history, interpretation of the family history with the medical history to assess the chance of disease occurrence or recurrence.
- Education of the patient and family regarding the inheritance, testing, management, risk reduction, available resources and research regarding the condition.
- Counseling to promote informed choices and appropriate interventions.

Genetic counseling can be conducted from preconception to old age. This includes preconception and prenatal counseling about the potential health of a baby, genetic evaluation of a neonate with birth defects or a toddler with developmental delay.

Family history: The initial step in assessing inherited risk for many chronic conditions is collecting data related to the family history.

Key factors that suggest the presence of a genetic disorder include the following:

- Multiple affected individuals in multiple generations from either side of the individual's family.
- Occurrence of the disease at an earlier age than usual.
- Close degree of relatedness (i.e., first- or second-degree relative) between affected relatives and the individual.

Once the family history is collected, it is used with the medical history to assess the possibility of an inherited etiology and to identify the chance of disease occurrence or recurrence.

Once an objective risk figure has been determined, the genetic counselor can provide explanations of penetrance and expressivity and apply these to the patient's family history and **assess personal risk**.

Risk modification: The genetic counseling session also provides information about risk modification strategies (if available) that may be appropriate for the patient and/or family. This may involve more aggressive screening (earlier, more frequent), lifestyle or dietary modifications, and medical or surgical interventions.

Examples include:

- **Familial cancer syndromes**: A patient with hereditary breast and ovarian cancer syndrome is at risk for both types of cancers and may have earlier mammography and clinical breast examinations and prophylactic surgeries.
- **Prenatal counseling**: Testing for the partner may be indicated for autosomal recessive conditions when a couple is referred for prenatal counseling.

Q. Write a short note on enzyme replacement therapy.

- **Enzyme replacement therapy** (**ERT**) is a type of treament which replaces an enzyme that is deficient or absent in the body. Enzymes can be made by recombinant DNA technology and can be given by intravenous injection.
- ERT has also been successful in treating SCID caused by an adenosine deaminase (ADA) deficiency.

Enzyme replacement therapy for diseases has been shown in **Table 23.11**.

TABLE 23.11: Enzyme replacement therapy for diseases.

Disease	***Enzyme therapy***
Fabry disease	Agalsidase beta
Gaucher disease	Imiglucerase
MPS I	Laronidase
MPS II	Idursulfase
MPS IVA	Elosulfase alfa
MPS VI	Galsulfase
Pompe disease	Alglucosidase alfa (160-L bioreactor)

CHAPTER 24

Clinical Pharmacology

INTRODUCTION

- Drug metabolism that varies on genetic basis is often called polymorphic drug metabolism **(Table 24.1)**.
- **Pharmacogenetics:** It is the study of individual gene-drug interactions, usually one or two genes that have a dominant effect on a drug response.
- **Pharmacogenomics** is the study of genomic influence on drug response.

TABLE 24.1: Genetic polymorphisms in drug metabolism.

Defect	***Enzyme involved***	***Drug***	***Consequences***
Oxidation	CYP2D6	Codeine	Reduced analgesia
Oxidation	Aldehyde dehydrogenase	Ethanol	Facial flushing, hypotension, tachycardia, nausea, vomiting
N-Acetylation	*N*-acetyltransferase	Isoniazid	Peripheral neuropathy
Ester hydrolysis	Plasma cholinesterase	Succinylcholine	Prolonged apnea
Oxidation	CYP2C9	Warfarin	Bleeding

ADVERSE DRUG REACTION

Definition: An unwanted or harmful reaction experienced following the administration of a drug or a combination of drugs under normal conditions of use and suspected to be related to the drug.

Adverse drug reaction (ADR) could be trivial or serious or fatal.

Classification of Adverse Drug Reaction (Table 24.2)

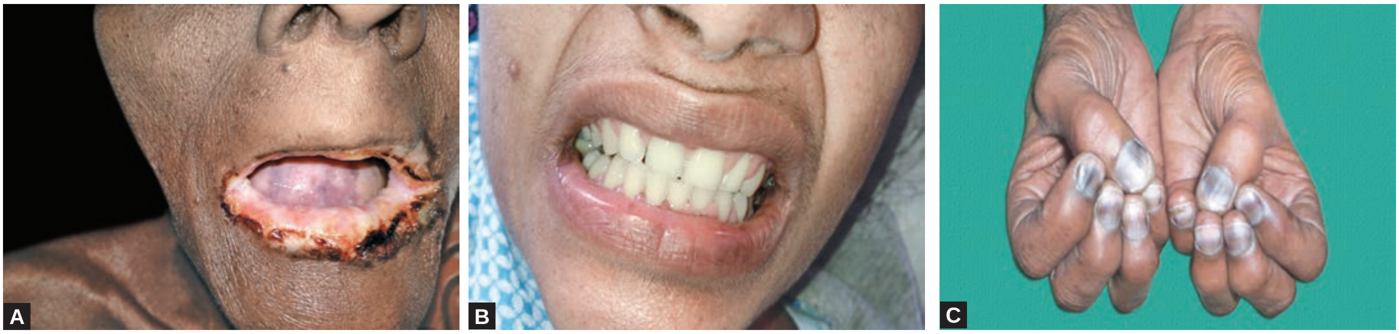
TABLE 24.2: Classification of adverse drug reactions (ADRs).

➢ ***Type A* (Augmented) reactions** – are predictable, often dose-dependent, and related to the pharmacokinetics (PK) of the drug – comprise up to 80% of all ADRs – e.g., hepatic failure due to overdose of acetaminophen, sedative side effects of antihistamines	➢ ***Type D* (Delayed) reactions** – are time related, uncommon, become apparent sometime after use of the drug – e.g., carcinogenesis, tardive dyskinesia, teratogenesis
➢ ***Type B* (Bizarre) reactions** – are unpredictable and are not related to the dose or the drug's PK – account for 10–15% of all ADRs	➢ ***Type E* (End of use) reactions** – are withdrawal, uncommon and occur soon after withdrawal of the drug – e.g., withdrawal syndrome with opiates/benzodiazepines
➢ ***Type C* (Chronic) reactions** – are chronic, dose related and time related, uncommon and related to cumulative dose – e.g., hypothalamic-pituitary-adrenal axis suppression by corticosteroids, osteonecrosis of the jaw with bisphosphonates	➢ ***Type F* (Failure) reactions** – are common, dose-dependent and caused by drug interactions – Cause an unexpected failure of therapy – e.g., inadequate dosage of an oral contraceptive when used with an enzyme inducer, resistance to antimicrobial agents

Severity of Adverse Drug Reaction

- **Minor:** No need of therapy, antidote or hospitalization.
- **Moderate:** Requires drug change, specific treatment, hospitalization.

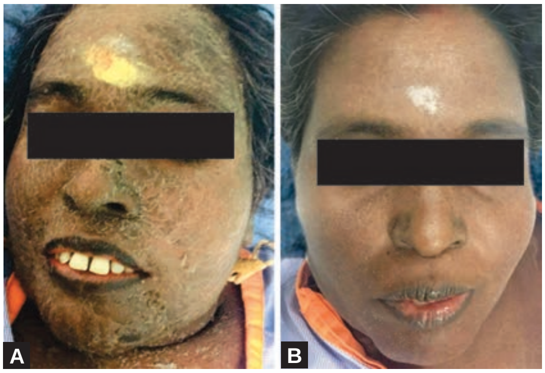
- **Severe:** Potentially life-threatening, permanent damage and prolonged hospitalization.
- **Lethal:** Directly or indirectly leads to death.



FIGS. 24.1A TO C: (A) Mucositis induced by anticancer drug; (B) Phenytoin-induced gum hyperplasia; (C) Zidovudine-induced nail pigmentation.

Types of Adverse Drug Reaction

- **Side effects:**
    - Unavoidable, predictable, decreased dose results in amelioration.
    - ***Occurs as extension of the same therapeutic effect,*** e.g., atropine as antisecretory in preanesthetic medication → dry mouth, mucositis induced by anticancer drug **(Fig. 24.1A)**.
    - ***Occurs as a distinctly different effect,*** e.g., promethazine as antiallergic—sedation, phenytoin-induced gum hyperplasia **(Fig. 24.1B)**, zidovudine-induced nail pigmentation **(Fig. 24.1C)**.
    - Estrogen as antiovulatory → nausea.
    - ***Side effect exploited for a therapeutic use,*** e.g., codeine (antitussive) constipating action used in diarrhea.
        - Sulfonylureas (tested as antibacterial) were found to decrease blood glucose.
- **Secondary effects:** Indirect effect of therapy. For example, intestinal microflora killed by tetracycline causing superinfection, corticosteroids decrease immunity causing oral candidiasis.
- **Toxic effects:** Overdose or prolonged use. Examples of toxic effects, overdosage or prolonged use includes atropine delirium, paracetamol → hepatic necrosis, barbiturates → coma, and morphine → respiratory failure.
- **Intolerance:** It is opposite of tolerance and characterized by increased sensitivity to low doses. Examples, few doses of carbamazepine → ataxia, single dose of triflupromazine → muscular dystonia.
- **Idiosyncrasy:** Genetically determined atypical or bizarre effect. Examples, barbiturate → excitement and mental confusion, streptomycin → deafness with single dose.
- **Drug reaction with eosinophilia and systemic symptoms (DRESS)** is a rare, potentially life-threatening, drug-induced hypersensitivity reaction that includes skin eruption, hematologic abnormalities (eosinophilia, atypical lymphocytosis), lymphadenopathy, and internal organ involvement (liver, kidney, lung). Common drugs associated are phenytoin, olanzapine, sulfonamides, febuxostat, dapsone, and vancomycin **(Figs. 24.2A and B)**.
- **Drug allergy or hypersensitivity:** Immunologically mediated, independent of dose and occurs in a small proportion of patients. Prior sensitization is required and occurs after 1–2 weeks after first dose. Drug acts as an antigen or hapten. Chemically-related drugs may show cross-sensitivity. Same drug can cause different allergic reactions in different individuals. Types of allergy include:
    - ***Type I*:** Urticaria **(Fig. 24.3)**, angioedema, asthma, anaphylactic shock.
    - ***Type II*:** Thrombocytopenia, agranulocytosis, aplastic anemia, systemic lupus erythematosus (SLE).
    - ***Type III*:** Arthralgia, lymphadenopathy, Stevens-Johnson syndrome.
    - ***Type IV*:** Contact dermatitis, fever, photosensitization, e.g., penicillin, sulfonamides, carbamazepine, and methyldopa.
- **Photosensitivity:**
    - ***Phototoxic*:** Drug accumulates in skin → absorbs light → photochemical reaction → photobiological reaction → tissue damage. Example, erythema, edema, blistering with *tetracyclines.*



[redacted]
[redacted]

FIGS. 24.2A AND B: Drug rash with eosinophilia and systemic symptoms (DRESS) syndrome: (A) Presteroid therapy; (B) Poststeroid therapy.

- *Photoallergic:* Drug → cell-mediated immune response → contact dermatitis on exposure to light, e.g., sulfonamides, griseofulvin.

- **Drug dependence:** Can be psychological and physical dependence.
- **Teratogenicity:** Drug use in pregnancy affects fetus. Examples, thalidomide → phocomelia, phenytoin → cleft palate.
- **Carcinogenicity and mutagenicity:** For example, anticancer drugs, estrogens.
- **Drug-induced diseases/iatrogenic diseases:** Examples, salicylates → peptic ulcer, phenothiazine → Parkinsonism, isoniazid (INH) → hepatitis.
- **Drug withdrawal reaction:** Examples, propranolol → hypertension, acute adrenal insufficiency following withdrawal of corticosteroids.

The management of ADR has been shown in **Table 24.3.**

TABLE 24.3: Management of adverse drug reaction.

Evaluation	***Supportive care***	***Enhancing elimination***
Airway	Respiratory	Activated charcoal
Breathing	Cardiovascular	Forced alkaline diuresis
Circulation	Central nervous system (CNS)	Hemodialysis/perfusion
Degree of consciousness		
History of exposure/ ingestion		
Physical examination		
Decontamination	***Diagnostic studies***	***Antidotes***
Gastric lavage	Blood tests	Organophosphates—atropine, oximes
Induction of emesis	Electrocardiogram (ECG)	Morphine—naloxone
Activated charcoal	X-rays	Benzodiazepines—flumazenil
Other decontamination	Specific drug levels	Paracetamol—*N*-acetylcysteine

The ways of preventing ADR are listed in **Box 24.1**.

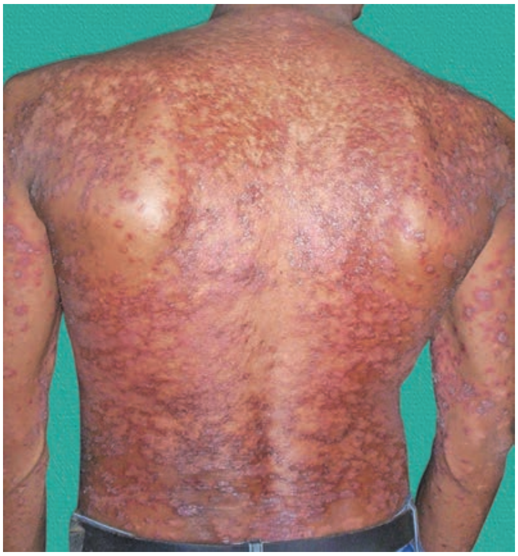


FIG. 24.3: Nevirapine-induced rash.

Box 24.1: Prevention of adverse drug reaction.

- Avoid inappropriate drugs in the context of clinical condition
- Use right dose, route, frequency-based on patient variables
- Elicit medication history; consider untoward incidents
- Elicit history of allergies (higher chances in patients with allergic diseases)
- Rule out drug interactions
- Adopt right technique, e.g., slow IV injection of aminophylline
- Carry out appropriate monitoring, e.g., prothrombin time (PT) with warfarin; drug levels

DRUG INTERACTION

Definition: A measurable modification (in magnitude and/or duration) of the action of one drug by prior or concomitant administration of another substance, including prescription, nonprescription (including complementary medicines) drugs, food, alcohol, cigarette smoking or diagnostic tests.

Outcomes of drug interaction are listed in **Box 24.2**.

Box 24.2: Outcomes of drug interaction.

- Loss of therapeutic effect
- Toxicity
- Unexpected increase in pharmacological activity
- Beneficial effects, e.g., additive and potentiation (intended) or antagonism (unintended)
- Chemical or physical interaction, e.g., intravenous incompatibility in fluid or syringes mixture

Mechanism of Drug Interaction

Pharmacokinetic Interaction

Altered gastrointestinal tract (GIT) absorption

- **Altered pH:** The nonionized form of a drug is more lipid soluble and more readily absorbed from GIT than the ionized form does. For example, antacids and H_2 blockers change gastric pH—decrease the dissolution of ketoconazole which requires acidic pH. Therefore, these drugs must be separated by at least 2 hours in the time of administration of both.
- **Altered intestinal bacterial flora:** In patients receiving digoxin, 40% or more of the administered dose is metabolized by the intestinal flora. If patients simultaneous take antibiotics which destroy the intestinal flora, digoxin toxicity can occur.
- **Complexation or chelation:** Tetracycline interacts with iron preparations → unabsorbable complexes. Decrease absorption of ciprofloxacin by 85% due to chelation, if given along with antacids.
- **Drug-induced mucosal damage:** Antineoplastic agents, e.g., cyclophosphamide, vincristine, procarbazine → mucosal damage and inhibit absorption of several drugs, e.g., digoxin.
- **Altered motility:** Metoclopramide (antiemetic) → increase absorption of cyclosporine due to the increase of stomach emptying time.

Displaced protein binding

- It depends on the affinity of the drug to bind to plasma protein.
- Phenytoin is highly bound to plasma protein (90%), tolbutamide (96%), and warfarin (99%). Drugs that displace these agents are aspirin, sulfonamides, and phenylbutazone.

Altered metabolism

- The effect of one drug on the metabolism of the other is well documented. The liver is the major site of drug metabolism but other organs can also be involved, e.g., white blood cell (WBC), skin, lung, and GIT.
- CYP450 family is the major metabolizing enzyme in phase I (oxidation process).
- Therefore, the effect of drugs on the rate of metabolism of others can involve the following examples:
  - ***Enzyme induction:***
    - A drug may induce the enzyme that is responsible for the metabolism of another drug or even itself, e.g., carbamazepine (antiepileptic drug) increases its own metabolism.
    - Phenytoin increases hepatic metabolism of theophylline → leading to decrease its level, reduces its action and vice versa.
  - ***Enzyme inhibition:***
    - It is characterized by reduction of the rate of metabolism of a drug by another drug. This leads to increased concentration of the target drug and thereby increases its toxicity.
    - Inhibition of the enzyme may be caused by the competition on its binding sites. This shortens the onset of action (may be within 24 hours).
    - Example, erythromycin inhibit metabolism of astemizole and terfenadine → raises the serum concentration of the antihistaminic and thereby increasing the cardiotoxicity which may be life-threatening.

First-pass Metabolism

- Administration of drug by oral route increases its metabolism in the liver and GIT. This causes loss of a part of the drug dose and decreases its action.
- This is more evident when such drug is an enzyme inducer or inhibitor.
- By increasing its first pass metabolism, rifampin reduces serum concentration of verapamil level. Also, rifampin induces the hepatic metabolism of verapamil.

Renal Excretion

Active tubular secretion

- It occurs in the proximal tubules (a portion of renal tubules).
- The drug combines with a specific protein and reaches the proximal tubules.
- When drug X has a competitive reactivity to the protein responsible for the active transport of drug Y, drug X will cause toxicity of Y due to a decrease in drug excretion of Y (increased concentration of Y).
- For example, probenecid → decreases tubular secretion of methotrexate.

Passive tubular reabsorption

- In the tubules, excretion and reabsorption of drugs is by passive diffusion and is regulated by concentration and lipid solubility.
- For example, sodium bicarbonate—increases lithium clearance and decreases its action.

Pharmacodynamic Interaction

- It indicates that there is alteration of the drug action without change in its serum concentration by pharmacokinetic factors.
- For example, **synergism** means = 1 + 1 = 3, **additive** means = 1 + 1 = 2, **potentiation** means = 1 + 0 = 2, and **antagonism** means = 1 + 1 = 0 or 0.5.

Prevention of Drug Interaction

- Monitoring therapy and making adjustments.
- Monitoring blood level of some drugs with narrow therapeutic index, e.g., digoxin, anticancer agents, etc.
- Monitoring of some parameters may help to detect the early events of interaction or toxicity. For example, with warfarin treatment, it is necessary to monitor the prothrombin time to adjust drug dosages.
- Increase the interest in case report studies to report different possibilities of drug interaction.

DRUGS AND LIVER

Common drugs metabolized in liver are mentioned in **Table 24.4**.

Cirrhotic Patients with Portosystemic Shunts

- Blood from intestines bypasses the liver, delivering much more of orally administered drugs to the systemic circulation. Thus, systemic bioavailability of orally administered high clearance drugs is much greater.
- *Hepatic impairment*:
  - Research has shown reduced drug-metabolizing enzyme (CYP and conjugation reactions) in cirrhosis which worsen disease severity (Child-Pugh score), but with large variability!
  - Preferentially recommend conjugatively metabolized agents in cirrhosis
  - In the absence of recommended doses:
    - *Child-Pugh A*: Reduce maintenance to 50%
    - *Child-Pugh B*: Reduce maintenance to 25%
    - *Child-Pugh C*: Use drugs proven safe, or drugs with level monitoring available.

TABLE 24.4: Common drugs metabolized in the liver.

Type of conjugation	*Endogenous reactant*	*Examples*
Glucuronidation	Uridine diphosphate (UDP)-glucuronic acid	Nitrophenol, morphine, acetaminophen, diazepam, N-hydroxydapsone, sulfathiazole, digitoxin, digoxin
Acetylation	Acetyl-CoA	Sulfonamides, isoniazid, clonazepam, dapsone, mescaline
Glutathione conjugation	Glutathione (GSH)	Acetaminophen, ethacrynic acid, bromobenzene
Glycine conjugation	Glycine	Salicylic acid, benzoic acid, cholic acid, deoxycholic acid
Sulfation	Phosphoadenosine phosphosulfate	Estrone, aniline, phenol, 3-hydroxycoumarin, acetaminophen, methyldopa
Methylation	S-adenosylmethionine	Dopamine, epinephrine, pyridine, histamine, thiouracil
Water conjugation	Water	Carbamazepine

DRUGS AND KIDNEY

Dosing of Drugs in Renal Failure

- Without careful dosing and therapeutic drug monitoring in patients with renal dysfunction, accumulation of drugs/toxic metabolites can occur. Drug dosing has to be adjusted to the calculated glomerular filtration rate (GFR).
- Renal disease affects the pharmacokinetic as well as pharmacodynamic (PD) effect of drugs.
- Uremia can alter drug disposition, protein binding, pharmacokinetics (PK), PD and can also increase sensitivity to drugs.

Effect of Renal Failure on Bioavailability

- Absorption of drugs in patients with renal disorders could be inhibited by gastrointestinal disturbances seen in uremia (nausea, vomiting, and diarrhea), uremic gastritis, and pancreatitis.
- Edema of GIT can occur with nephrotic syndrome and impair absorption.
- Gastric motility can be impaired by uremia.
- Uremia can also increase gastric ammonia and lead to increased gastric pH thus affecting drugs that require acidic pH for absorption (e.g., ferrous sulfate).
- First-pass effect is reduced in patients with renal disease (therefore, absorption of drugs with high first-pass effect is increased, e.g., propranolol).

Effect of Renal Failure on Protein Binding and Volume of Distribution

- The effect of a drug is related to the amount of free or unbound drug available to target tissues.
- Also, hypoalbuminemia is common in patients with renal failure. Therefore, highly protein binding drug has fewer albumins to cling to. This is especially important with phenytoin.

Elimination

- As kidney disease progresses, the kidney's ability to excrete uremic toxins decreases as does its ability to eliminate certain drugs.
- Kidney eliminates primarily through filtration or active secretion.
- Drugs with low protein binding are filtered more readily.
- Large molecules (molecular weight > 20,000 daltons) are not readily filtered due to its size.

Drug Removed by Dialysis

- Removal by dialysis is specific to each drug.
- *Factors affecting removal*: Type of machine, membrane surface area, pore size, flow rates.

- Dialysis is sometimes used to remove excess drug in an overdose situation.

DRUG USAGE IN PREGNANCY

- The safety of approximately 50% of medications for the mother and fetus remains unknown.
- Pharmacokinetics are profoundly affected by pregnancy-associated physiological changes and dose adjustments are sometimes necessary for optimal clinical outcome.

Current Categories for Drug Use in Pregnancy (FDA) (Table 24.5)

Few drugs contraindicated during pregnancy and those which have teratogenic effects are listed in **Table 24.6**. Common problems in pregnancy and drugs that can be safely used in these cases are mentioned in **Table 24.7**.

CLINICAL TRIALS BASIC CONCEPTS

Clinical trial is an experimental epidemiological method. It is an interventional study on individuals, usually on patients.

Objectives of Clinical Trials

- Intervention trials determine whether experimental treatments are safe and effective under controlled environments.
- Observation trials address health issues in large groups of people in natural settings.

Levels of Evidence (Table 24.8)

Levels of evidence (sometimes called hierarchy of evidence) are assigned to studies based on the methodological quality of their design, validity, and applicability to patient care. These decisions give the "grade (or strength) of recommendation".

TABLE 24.5: Current categories for drug use in pregnancy.

Category	*Description*
A	Adequate, well-controlled studies in humans show no risk to the fetus (e.g., magnesium sulfate)
B	No well-controlled studies have been conducted in humans. Animal studies show no risk to the fetus (e.g., amoxicillin, amoxicillin + clavulanic acid, cefotaxime, methyldopa, metronidazole, erythromycin)
C	No well-controlled studies have been conducted in humans. Animal studies have shown an adverse effect on the fetus (e.g., diclofenac, rifampicin, fluoroquinolones, aminoglycosides, glyburide)
D	Human studies have demonstrated a risk to the fetus. However, the benefits of therapy may outweigh the potential harm [e.g., tetracyclines, phenytoin, valproic acid, carbamazepine, angiotensin-converting enzyme (ACE) inhibitors]
X	Controlled studies in animals or humans have demonstrated fetal abnormalities. The use of the product is contraindicated in women who are or may become pregnant (e.g., thalidomide, oral contraceptive pills, misoprostol)

TABLE 24.6: List of few drugs contraindicated during pregnancy and those which have teratogenic effects.

Drug	*Side effects*
Tetracycline	Yellow staining of the primary or deciduous teeth and diminished growth of the long bones
Phenytoin	Fetal hydantoin syndrome consisting of intrauterine growth retardation (IUGR), microcephaly, mental retardation, distal phalangeal hypoplasia
Retinoic acid	Craniofacial dysmorphisms, cleft palate, thymic aplasia, and neural tube defects
Thalidomide	Meromelia, absence of the limbs to rudimentary limbs to abnormally shortened limbs
Alcohol	IUGR, small head, small eyes or short eye openings, or a poorly developed philtrum and congenital heart disease
Nicotine	Intrauterine growth retardation
Warfarin	Nasal hypoplasia and a depressed nasal bridge, stippled epiphysis; termed fetal warfarin syndrome
Estrogen and androgens	Genital tract malformations
Chloramphenicol	Gray baby syndrome

TABLE 24.7: Common problems in pregnancy and drugs that *can be safely used.*

Common problems in pregnancy	*Drugs that can be safely used*
Nausea and vomiting	Pyridoxine, meclizine diphenhydramine
Constipation	Mild purgative-like senna
Peptic ulcer	Sucralfate, H_2 blockers
Hematopoietic (iron and folic acid deficiency)	Iron and folic acid
Urinary tract infections	Ampicillin, amoxicillin, cefuroxime axetil
Other infections	β-lactam antibiotics, cephalosporins
Malaria	Chloroquine, quinine, proguanil
Amoebiasis	Metronidazole and diloxanide furoate
Worm infestation	Piperazine citrate, pyrantel pamoate
Fungal infection	Miconazole, clotrimazole, nystatin
Human immunodeficiency virus (HIV) infection	None of the anti-HIV drugs are safe, except zidovudine and nevirapine
Tuberculosis	INH and ethambutol are safe. If third drug is needed, then rifampicin
Diabetes mellitus	Insulin
Hypothyroidism	Thyroxine
Thyrotoxicosis	Propylthiouracil
Hypertension	α-methyldopa, in emergency—hydralazine, β-blockers—labetalol, atenolol
Thromboembolic disease	Heparin
Headache and inflammatory condition	Paracetamol, avoid other nonsteroidal anti-inflammatory drugs (NSAIDs)
Epilepsy	Sodium valproate and phenytoin to be avoided, carbamazepine in lower dose can be used
Migraine	Paracetamol, propranolol, amitriptyline
Antidepressants	Amitriptyline and imipramine

TABLE 24.8: Levels of evidence.

Level of evidence (LOE)	*Description*
Level I	Evidence from a **systematic review or meta- analysis** of all relevant RCTs (randomized controlled trials) or evidence-based clinical practice guidelines based on systematic reviews of RCTs or three or more RCTs of good quality that have similar results
Level II	Evidence obtained from at least one well-designed **RCT** (e.g., large multisite RCT)
Level III	Evidence obtained from well-designed **controlled trials without randomization** (i.e., quasi- experimental)
Level IV	Evidence from well-designed **case-control or cohort studies**
Level V	Evidence from systematic reviews of descriptive and qualitative studies (metasynthesis)
Level VI	Evidence from a single descriptive or qualitative study
Level VII	Evidence from the opinion of authorities and/or reports of expert committees

Features of observational and experimental studies are mentioned in **Table 24.9**.

TABLE 24.9: Features of observational and experimental studies.

Observational studies	*Experimental studies*
Cross-sectional, case series, case-control studies, cohort studies ➢ Identify participants ➢ Observe and record characteristics ➢ Look for associations	Before and after studies, comparative trials (controlled or head-to-head), randomized trials ➢ Identify participants ➢ Place in common context ➢ Intervene ➢ Observe/evaluate effects of intervention

Types of Study

Q. CM6.3 **Describe, discuss and demonstrate the application of elementary methods including test of significance in various study designs.**

The types of study have been shown in **Table 24.10**.

TABLE 24.10: Types of study with its pros and cons.

Types of study	*Description*	*Pros*	*Cons*
RCT (randomized controlled trial)	An experimental comparison study where participants are allocated to treatment/intervention or control/ placebo groups using a random mechanism. Best for studying the effect of an intervention	Unbiased distribution of confounders. Blinding more likely. Randomization facilitates statistical analysis	*Expensive*: Time and money. Volunteer bias Ethically problematic at times
Crossover trial	A controlled trial where each participant has both therapies, i.e., randomized to treatment A first then starts treatment B	➢ All participants serve as own controls and error variance is reduced, thus reducing sample size needed. All participants receive treatment (at least some of the time). ➢ Statistical tests assuming randomization can be used. Blinding can be maintained	All participants receive placebo or alternative treatment at some point. Washout period lengthy or unknown. Cannot be used for treatments with permanent effects
Cohort study	Data obtained from groups who have already been exposed, or not exposed, to the factor of interest. No allocation of exposure is made by the researcher. Best for studying effects of *risk factors on an outcome*	➢ Ethically safe ➢ Participants can be matched ➢ Can establish timing and directionality of events ➢ Eligibility criteria and outcome assessments can be standardized	➢ Controls may be difficult to identify. Exposure may be linked to a hidden confounder. Blinding is difficult ➢ For rare disease, large sample sizes or long follow-up necessary
Case-control study	Patients with a certain outcome or disease and an appropriate group of controls, without the outcome or disease, are selected (usually with some matching); then information is obtained on whether the subjects have been exposed to the factor under investigation	Quick and cheap as fewer people needed than cross-sectional studies. Only feasible method for very rare disorders or those with long lag between exposure and outcome	➢ Reliance on recall or records to determine exposure status confounders ➢ Selection of control groups is difficult. ➢ *Potential bias*: Recall, selection
Cross-sectional study	Examines the relationship between (1) diseases/other health-related characteristics and (2) other variables of interest as they exist in defined population at one time. Exposure and outcomes both measured at the same time. Quantifies prevalence, risk, or diagnostic test accuracy	Cheap and simple. Ethically safe	➢ Establishes association at most, not causality ➢ Recall bias, social desirability bias, Researcher's (Neyman) bias. Group sizes may be unequal. Confounders may be unequally distributed

Phases of Clinical Trials

Most trials that involve new drugs go through a series of steps:

- Experiments in the laboratory.
- Once deemed safe, go through 1–4 phases.
    - **Phase I:** Small group (20–80) for 1st time to evaluate safety, determine safe dosage range and identify side effects.
    - **Phase II:** Treatment given to larger group (100–300) to confirm effectiveness, monitor side effects, and further evaluate safety.
    - **Phase III:** Treatment given to even larger group (1,000–3,000) to fulfill all of phase II objectives and compare it to other commonly used treatments and collect data that will allow it to be used safely.
    - **Phase IV (postmarketing surveillance):** Done after treatment has been marketed—studies continue to test treatment to collect data about effects in various populations and side effects from long-term use.

Informed Consent

Informed consent document will be obtained from the participants in the study population after explaining them fully about: (1) the purpose; (2) duration; (3) required procedures; (4) expectations; (5) risks and benefits; (6) adverse effects of the trial if any, and (7) participants rights.

It is a continuous process throughout the study of learning of key facts by participants about a clinical trial. It also explains the rights of the participant. It is not a contract and the participant can withdraw from the trial at any time.

Ethical Aspects

- Participants are human beings with a motive to help the researcher and society.
- Researcher should never be overenthusiastic in his intervention to get his results while dealing with participants.
- Informed consent is not having a legal binding on the patients. It is a communication document.

Random Allocation

The participants in the study population are randomly allocated into two groups (arms) using random number tables to avoid selection and confounding biases.

Purpose of randomization: This elimination of allocation bias will greatly enhance the validity of the trial.

Blinding

The investigator, the participant and sometimes even the evaluator are all kept unaware (blinded) of the outcomes of the trial and secrecy is maintained to improve the validity.

Purpose of blinding: Blinding or masking is done to eliminate: (1) investigator bias; (2) evaluation bias and (3) Hawthorne effect.

Types of Blinding

The types of blinding is shown in **Table 24.11**.

TABLE 24.11: Types of blinding and their descriptions.

Types	*Description*
Unblinded or open label	All parties are aware of the treatment the participant receives
Single blind or single-masked	Only the participant is unaware of the treatment they receive
Double blind or double-masked	The participant and the clinicians/data collectors are unaware of the treatment the participant receives
Triple blind	Participant, clinicians/data collectors and outcome adjudicators/data analysts are all unaware of the treatment the participant receives

Unblinding

In emergencies and life-threatening situations for participants, unblinding can be done.

Assessment Criteria

- Whether the outcomes or endpoints are single or multiple, subjective or objective, uniform and similar type of evaluation of endpoints for both the groups is to be carried out.
- Subjectivity of the outcome, e.g., reduction of pain, may lead to observer error and poor assessment.
- Double blinding eliminates observer bias to a large extent.

Intention-to-treat Principle

Whole of the experimental population including nonparticipants, once randomized, whether they are participating or not in the trial, have to be considered for evaluation as our intention is to treat all the people randomized.

Placebo Effect or Attention Bias

Psychological relief of symptoms, not true biological relief, is often reported. Neurophysiologically there is an increase of dopamine and opioids in people experiencing placebo effects.

Nocebo Effect

- These are adverse events produced by negative expectations. These are observed not only in everyday clinical practice, but also in clinical trials.
- Neurophysiologically there is decrease in dopamine, but increase in cortisol and cholecystokinin (CCK) in people experiencing nocebo effect.
- These nonspecific side-effects distress patients, add to the burden of their illness, and increase the costs of their care.
- They may lead to nonadherence, cause physicians to discontinue what is otherwise an appropriate therapy or prompt attempts to treat these side-effects with additional drug.

Hawthorne Effect

- Sometimes the participants in comparison group may exaggerate the effects/outcomes to please the investigator or when they like the study or for some other reasons. Investigator does more frequent follow-up of exposed group in order to establish the cause.
- This will affect the assessment unless controlled.

CHAPTER

25

Emergencies and Critical Care

CASE 1: MANAGEMENT OF SEVERE HYPERKALEMIA

Q. IM22.8 Enumerate the causes and describe the clinical and laboratory features and the correct approach to the diagnosis and management of the patient with hyperkalemia.

Q. IM10.18 Identify the ECG findings in hyperkalemia.

History

An 80-year-old male found collapsed at home, incontinent of urine and feces. He is a known case of hypertension (HTN) and congestive cardiac failure (CCF); he is on enalapril for HTN, spironolactone and metoprolol for CCF.

Examination

Patient is confused and combative.

Vitals:

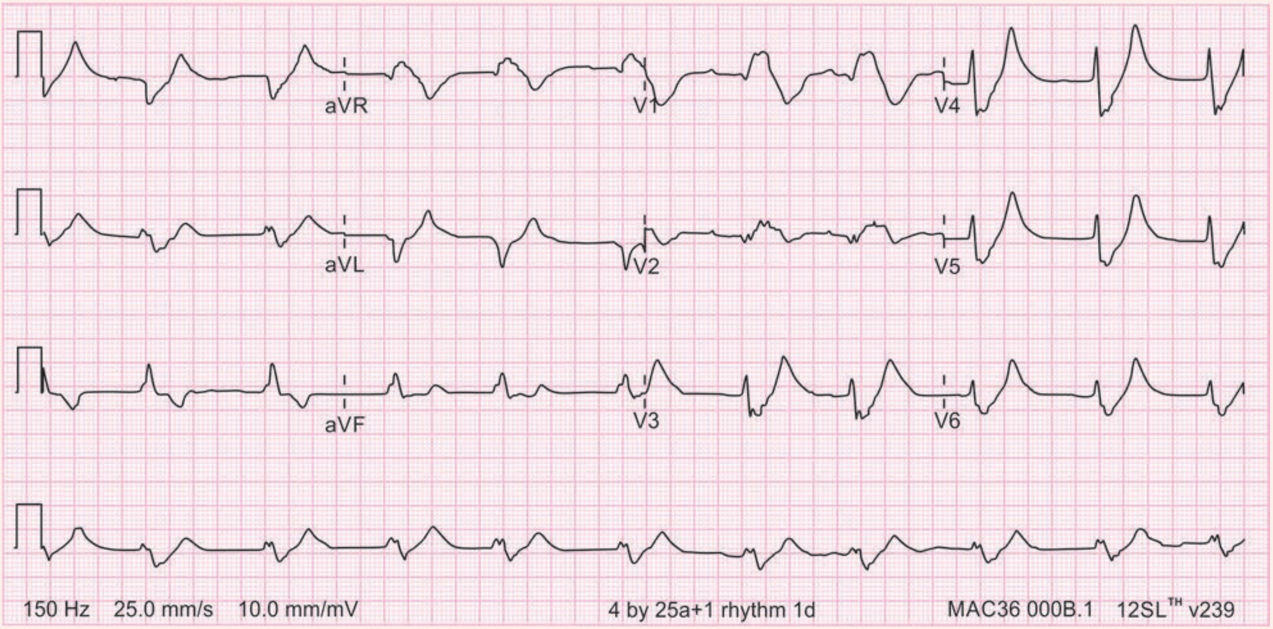
BP: 78/60 mm Hg	PR: 60 bpm	RR: 32/min	SpO_2: 91%

GCS: 13

Investigations

pH: 7.23	K^+: 7.0 mEq/L	Blood glucose: 189 mg/dL

ECG: ECG shows absent P waves, broad QRS complexes and tall tented T waves suggestive of hyperkalemia.



aVR
V1
V4
aVL
V2
V5
aVF
V3
V6
150 Hz 25.0 mm/s 10.0 mm/mV
4 by 25a+1 rhythm 1d
MAC36 000B.1 12SL™ v239

Management	
Immediate antagonism of cardiac effects of hyperkalemia: **Membrane stabilization**	Calcium gluconate 10%, 10 mL slow IV over 10 minutes Calcium chloride 3–4 mL
Rapid reduction in plasma K^+ by redistribution into the cells	IV 50 mL of 50% dextrose + 10 units of regular insulin 10–20 mg of nebulized albuterol in 4 mL NS inhaled over 10 minutes
Removal of K^+ from the body	Ion exchange resin: Sodium polystyrene sulfonate 15–30 g powder—given in a premade suspension with 33% sorbitol, IV furosemide and NS, hemodialysis

CASE 2: METABOLIC ACIDOSIS

Q. IM22.9 Enumerate the causes and describe the clinical and laboratory features of metabolic acidosis.

History

A 56-year-old man with a history of alcohol use presents with a 4-day history of severe abdominal pain, nausea, and vomiting.

Examination

Vitals:

BP: 80/50 mm Hg	Epigastric tenderness +

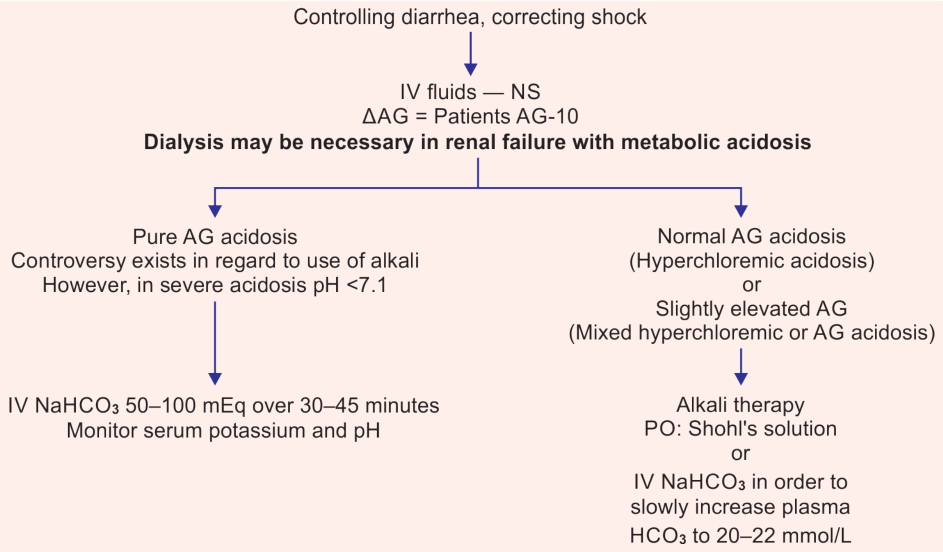
Investigations

Electrolytes:		**Serum biochemistry:**			**Arterial blood gas:**	
Na: 132 mEq/L	K: 3.8 mEq/L	Creatinine: 1.5 mg/dL	Amylase: 400 U/L	Lipase: 250 U/L	pH: 7.28	PCO_2: 34 mm Hg
Cl: 92 mEq/L	HCO_3: 16 mEq/L				PO_2: 88 mm Hg	HCO_3: 16.3 mEq/dL

Identify and treat the underlying cause

Determine ΔAG

Management



Controlling diarrhea, correcting shock
IV fluids — NS
ΔAG = Patients AG-10
Dialysis may be necessary in renal failure with metabolic acidosis
Pure AG acidosis
Controversy exists in regard to use of alkali
However, in severe acidosis pH <7.1
IV NaHCO₃ 50–100 mEq over 30–45 minutes
Monitor serum potassium and pH
Normal AG acidosis
(Hyperchloremic acidosis)
or
Slightly elevated AG
(Mixed hyperchloremic or AG acidosis)
Alkali therapy
PO: Shohl's solution
or
IV NaHCO₃ in order to
slowly increase plasma
HCO₃ to 20–22 mmol/L

(AG: anion gap)

CASE 3: HYPOGLYCEMIA

Q. IM11.22 Enumerate the causes of hypoglycemia and describe the counter hormone response and the initial approach and treatment.

Q. M11.14 Recognize the presentation of hypoglycemia and outline the principles on its therapy.

History

A 32-year-old patient with altered level of consciousness. History of mellitus, on insulin.

Examination

GCS: 10 (E3, V3, M4)

Vitals:

Pulse: 72 bpm	BP: 100/56 mm Hg	SpO_2: 98%

Investigations

Blood sugar: 32 mg/dL

Management

Mild	***Severe***
If detected early, and patient is able to take and tolerate orally, carbohydrates orally in an easily absorbable form should be given.	Dextrose 75 mL of 20% dextrose IV Oral carbohydrate to be given as soon as the patient is able to eat Glucagon 0.5–1 mg SC/IM Octreotide Identify and treat the cause: ➢ Adjusting the dose of oral hypoglycemic agents (OHA), insulin ➢ Changing the timing of insulin injection

CASE 4: MANAGEMENT OF ACUTE PULMONARY EDEMA

History

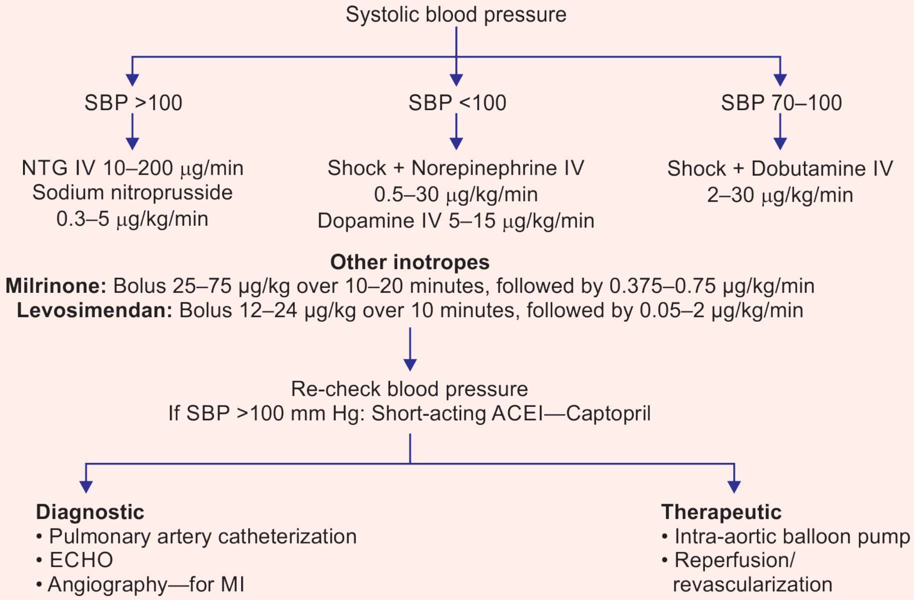
A 62-year-old elderly male patient came with complaints of sudden severe shortness of breath.
Past history: MI—6 months back

Examination

Patient is sitting leaning forward. He is pale, distressed, and sweaty. Productive pink tinged frothy sputum. **Vitals:** Pulse: 140 bpm BP: 200/110 mm Hg RR: 38/min SpO_2: 78%	Bilateral pedal edema present up to ankle level **Cardiovascular system:** Gallop rhythm **Respiratory System:** Basal crepitations present bilaterally

Management

Monitor vitals
Oxygen: Noninvasive positive pressure ventilation or intubation and mechanical ventilation
Furosemide 0.5–1 mg/kg IV bolus
Morphine 2–4 mg IV



Systolic blood pressure
SBP >100
SBP <100
SBP 70–100
NTG IV 10–200 µg/min
Sodium nitroprusside
0.3–5 µg/kg/min
Shock + Norepinephrine IV
0.5–30 µg/kg/min
Dopamine IV 5–15 µg/kg/min
Shock + Dobutamine IV
2–30 µg/kg/min
Other inotropes
Milrinone: Bolus 25–75 µg/kg over 10–20 minutes, followed by 0.375–0.75 µg/kg/min
Levosimendan: Bolus 12–24 µg/kg over 10 minutes, followed by 0.05–2 µg/kg/min
Re-check blood pressure
If SBP >100 mm Hg: Short-acting ACEI—Captopril
Diagnostic
• Pulmonary artery catheterization
• ECHO
• Angiography—for MI
Therapeutic
• Intra-aortic balloon pump
• Reperfusion/ revascularization

CASE 5: MANAGEMENT OF SEVERE HYPERCALCEMIA

Q. IM22.3 Describe the approach to the management of hypercalcemia.

History

An 80-year-old woman presented with vomiting, diarrhea, fatigue, malaise, generalized abdominal pain, and weight loss. K/c/o metastatic breast cancer.

Examination

Vitals:
Pulse: 98 bpm BP: 90/70 mm Hg RR: 14/min
Per abdomen: Generalized abdominal tenderness present

Investigations

Serum calcium >11 mg/dL

Management

Intravenous normal saline	4–6 L may be required over first 24 hours
Bisphosphonates	Inhibit bone resorption: ➢ Zoledronic acid 4 mg IV over 30 minute ➢ Pamidronate 60–90 mg IV over 2–4 hours ➢ Ibandronate 2 mg IV over 2 hours
Calcitonin	Increases calcium excretion 100 U; 3 times/day; IM/SC for first 24–48 hours
Gallium nitrate	➢ 200 mg/m^2 IV daily for 5 days ➢ Alternative to bisphosphonates ➢ Nephrotoxic
Dialysis	

CASE 6: TENSION PNEUMOTHORAX

History

A 23-year-old man presents with a single gunshot wound to the right side of his chest.

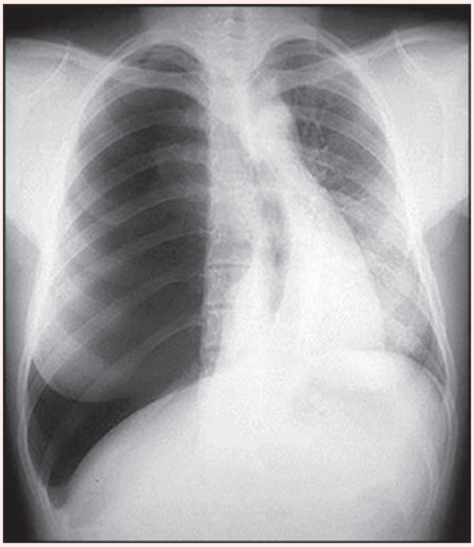
Examination

Patient is conscious.
Central cyanosis
Vitals:
Pulse: Palpable, rapid, thread
BP: 90/60 mm Hg
RR: 30/min, rapidly progressing dyspnea

Respiratory system:
Trachea deviated to the left
Jugular veins are distended
Palpable crepitus
Decreased chest movements on right side
Percussion—hyper-resonance on right side
Decreased/absent breath sounds and vocal resonance on right side

Investigations

Chest X-ray: Chest X-ray revealing right-sided tension pneumothorax



Management

Insertion of wide bore needle into pleural space through the anterior 2nd ICS. Needle is left in place till a thoracostomy tube is inserted

OR

Insertion of a wide bore plastic cannula, attached to a long rubber tubing, end of which is placed underwater

↓

Insertion of intercostal drainage tube in 4th/5th/6th ICS in mid-axillary line connected to an underwater seal or one-way Heimlich valve

CASE 7: MYXEDEMA COMA

History

A 47-year-old female patient known case of hypothyroidism presented with complaints of falls, leg edema and pain, drowsiness, headaches, and shortness of breath.

Examination

Vitals:
Pulse: 50 bpm BP: 90/70 mm Hg
RR: 20/min

Periorbital edema is present.
Nonpitting edema is present.
Central nervous system: Delayed tendon reflexes

Investigations

Thyroid function:
Free T_3: 0.05 ng/dL (0.93–1.7)
TSH: 30.12 MIU/mL (0.27–5.0)

Na^+: 121 mEq/L
K^+: 4.2 mEq/L
Cl^-: 87 mEq/L

Other investigations required:
T4, CPK, ABG, RBS, sepsis screening

Management

Treatment must be initiated even before biochemical confirmation of diagnosis
Monitor vitals—temperature
Levothyroxine 500 µg IV bolus or **Tri-iodothyronine** 10–25 µg every 8–12 hourly IV; followed by oral levothyroxine 50–100 µg daily
Hydrocortisone 100 mg IV TID
Slow rewarming
Cautious use of **IV fluids**: Hypotonic fluids to be avoided because they can increase water retention. Broad-spectrum antibiotics
High flow oxygen
Identify and treat the cause

CASE 8: THYROTOXIC CRISIS/THYROID STORM

History

A 39-year-old woman presented with a 3-month history of increased sweating and palpitations with weight loss of 7 kg. She had family history of thyroid disease.

Examination

Vitals:
Pulse: 122 bpm BP: 130/80 mm Hg RR: 20/min
Warm and moist skin. Her thyroid gland is enlarged bilaterally. Bilateral exophthalmos present.
Systemic examination: CVS: Tachycardia present PA: Generalized abdominal tenderness

Investigations

T4: 12.00 ng/dL (0.73–1.84)
T3: 1173.00 ng/dL (123–211 ng/dL)
TSH <0.018 µIU/mL
T3, T4, TSH, sepsis screen, LFT, ECG

Management

Rehydrate
Propranolol: Given orally: 60–80 mg 4 times a day. IV: 1–5 mg 4 times a day
Propylthiouracil: Loading dose: 500–1000 mg followed by maintenance dose of 250 mg 4th hourly oral or via NG tube
Carbimazole: 15–30 mg stat followed by 15 mg TID
Lugol's iodine: 10 drops TID—1 hour after PTU/carbimazole
Sodium ipodate: 500 mg/day orally
Hydrocortisone: 200 mg IV bolus followed by 100 mg every 8th hourly
Oxygen, IV fluids, external cooling
Identify and treat the cause
Antibiotics if infection is present.

CASE 9: ACUTE ADRENAL INSUFFICIENCY

Q. PA32.7 **Describe the etiology, pathogenesis, manifestations, laboratory, morphologic features, complications of adrenal insufficiency.**

History

A 38-year-old female is admitted for complaints of progressive fatigue for 2 weeks. She also complains of nausea and vomiting. History of loss of 8 kg in the past 2 weeks. History of recent onset of breathlessness.

Examination

Vitals:
Pulse: 134 bpm BP: 80/40 mm Hg
RR: 18/min Temperature: 99°F

Appears pale, dehydrated, and malnourished
Systemic examination: Unremarkable

Investigations

Na$^+$: 120 mmol/L K$^+$: 5.9 mmol/L	Hb: 12.4 g/dL WBC: 11,600 and mild eosinophilia

Management

Monitor vitals
Rehydration
Normal saline IV infusion: 1 L/hr with continuous cardiac monitoring
Draw blood for plasma cortisol and blood sugars
Hydrocortisone: 100 mg IV bolus, followed by 100 mg 6th hourly for the first 24 hours and continue parenterally till patient can take orally.
Treat hypoglycemia and hyperkalemia
Treat the precipitating cause

CASE 10: COMA

Investigations

CBC, RBS, electrolytes LFT, RFT, ABG, blood culture, CXR, ECG, CT scan, drug screen if indicated

Management

General measures	*Specific treatment*	*Long-term management*
➢ Monitor vitals ➢ Protect the airway: Oropharyngeal airway/intubation if needed ➢ Avoid secondary insults to the brain like hypoxia, hypoglycemia, and hypotension ➢ Secure IV access: Hypotonic IV fluids with close monitoring	➢ Hypoglycemic coma: Thiamine followed by dextrose ➢ Fever and meningismus indicate urgent need for CSF analysis followed by IV antibiotics	➢ Frequent change of position every 2–3 hourly to avoid bedsores ➢ Lid taping ➢ Catheterization ➢ Prevent aspiration by positioning the patient left lateral

CASE 11: SNAKEBITE

Q. FM11.1 Describe features and management of snakebite.

A 24-year-old farmer brought to the casualty with history of snakebite 3 hours back.

Management

- Reassure the patient
- Immobilize the bitten limb
- **Investigations:** Whole blood clotting time (**WBCT),** CBC, coagulation screen, RFT, electrolytes, CPK, ECG, urine routine examination (URE), FDP, fibrinogen level
- Monitor vitals
- Input/output (I/O) charting
- Secure IV access
- Antisnake venom (ASV) if indicated:
  - Mild cases: 5 vials
  - Moderate cases: 5–10 vials
  - Severe cases: 10–20 vials
- Given as IV infusion in 5–10 mL/kg of NS and given over 1 hour
- **Never give locally at the site of snakebite**
- Keep adrenaline ready in case of anaphylaxis
- For coagulopathy: FFP/cryoprecipitate/platelet concentrate
- In case of neurotoxic snakebite: If there is respiratory failure or bulbar paralysis:
  - Intubation and mechanical ventilation
  - Give injection glycopyrrolate 0.25 mg
  - Followed injection neostigmine IV infusion 50–100 mg/kg/4 hours
- Antibiotic prophylaxis
- Anti-tetanus prophylaxis
- Renal failure managed with hemodialysis

CASE 12: HYPOVOLEMIA

History

A 50-year-old male is brought in an ambulance, following road traffic accident 45 minutes prior, with a penetrating injury to the thigh.

Investigations

Hemoglobin, hematocrit, BUN, creatinine, electrolytes, ABG, urinary sodium

Management

Monitor vitals
Secure IV line
Strict I/O charting
Mild hypovolemia can be treated with oral hydration.
Severe hypovolemia requires intravenous hydration, give isotonic normal saline – 0.9% NaCl (154 mM Na^+).
Calculation of free water deficit:

$$\text{Free water deficit} = \text{Total body water} \times \frac{[\text{plasma sodium}-1]}{140}$$

50% of this calculated deficit is given over the first 24 hours and the remaining over the next 24 hours.
Patients with bicarbonate loss and metabolic acidosis may need IV bicarbonate.
Patients with severe hemorrhage should receive red cell transfusion without increasing hematocrit >35%.
Identify and treat the cause of hypovolemia.

CASE 13: MANAGEMENT OF SHOCK

Q. PH1.27 Describe the mechanisms of action, types, doses, side effects, indications and contraindications of drugs used in shock.

History

A 25-year-old male patient is admitted to ICU with 3 days old perforation. History of chills and fever is present.

Examination

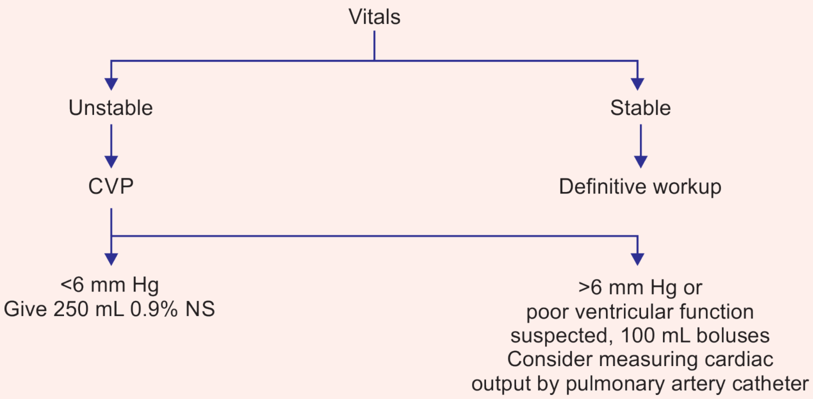
Mental status is altered, restless
Vitals:
Pulse: 130 bpm BP: 80/60 mm Hg RR: 40/min
Skin—warmed and flushed

Investigations

Hemoglobin, hematocrit, sepsis screen, LFT, RFT, electrolytes, ABG

Management

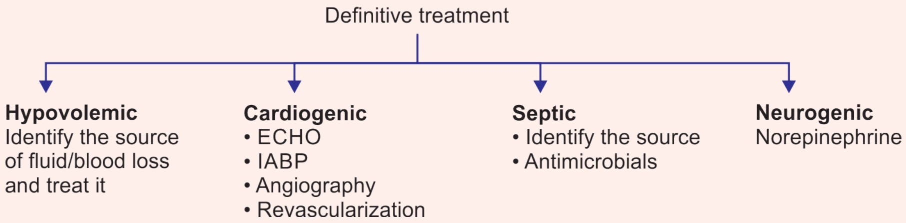
Secure IV access
Assess GCS, qSOFA score
Oxygen/intubation and mechanical ventilation if needed, e.g., GCS <8



Vitals
Unstable
Stable
CVP
Definitive workup
<6 mm Hg
Give 250 mL 0.9% NS
>6 mm Hg or
poor ventricular function
suspected, 100 mL boluses
Consider measuring cardiac
output by pulmonary artery catheter

Monitor vitals, I/O charting, peripheral perfusion
Optimize Hb: Transfuse red cells
Achieve target BP: Inotropes once the hypovolemia is corrected

- Dobutamine: 2–8 μg/kg/min
- Adrenaline: 1–8 μg/kg/min
- Refractory hypotension: Add Inj. Hydrocortisone 50 mg IV Q6H



Definitive treatment
Hypovolemic
Identify the source
of fluid/blood loss
and treat it
Cardiogenic
• ECHO
• IABP
• Angiography
• Revascularization
Septic
• Identify the source
• Antimicrobials
Neurogenic
Norepinephrine

CASE 14: ISCHEMIC STROKE

History

A 41-year-old male patient, alcoholic, k/c/o hypertension presents to casualty with chief complaint of right-sided weakness, slurred speech, and loss of balance. Symptoms began 90 minutes prior to arrival.

Examination

Vitals:		**CNS:**	
Pulse: 88 bpm, irregular	BP: 178/90 mm Hg	Right side facial weakness	Power is reduced on right side
RR: 18/min	GCS: 11/15	No sensory deficit on right side	Plantar extensor on right side

Investigations

Plain CT brain, RBS, electrolytes, ECG, suspected AF → thyroid function tests, ECHO

Management

General measures	Airway—ensure airway patency Breathing—O_2 if SpO_2 is < 95% Circulation—check PR, BP. Secure IV access. Treat abnormalities with IV fluids/antiarrhythmics/inotropes Look for hypoglycemia and treat accordingly
IV thrombolytics	Intravenous rtPA within 3 hours of onset of ischemic stroke Dose: 0.9 mg/kg → 10% of total dose as IV bolus, remaining as IV infusion over 60 minutes
Endovascular mechanical thrombectomy	If IV thrombolysis is contraindicated or has failed
Antiplatelets	Aspirin 75–150 mg OD
Statins	Atorvastatin, rosuvastatin 10–20 mg OD
Medical support	Catheterization RT feeding Treat fever with antipyretics, surface cooling Pneumatic compression stockings Prevent bedsores and contractures Initiate secondary preventive measures
Rehabilitation	Early physiotherapy, occupational/speech therapy

CASE 15: HYPERVENTILATION

History

A 21-year-old girl, k/c/o anxiety disorder, going for examinations, presents with perioral tingling. She has carpopedal spasms.

Investigation

Arterial blood gas: Reveals respiratory alkalosis

Management

Identify and treat the initiating factor
Reassurance
Rebreathing into a closed bag
If there is associated palpitations/tremors: β-blockers
Identifying and eliminating habits that perpetuate hypocapnia such as sigh breathing
Breathing exercises, diaphragmatic retaining may be helpful.

CASE 16: ACUTE PULMONARY EMBOLISM

History

A 71-year-old woman bedridden for last 4 days following fall and trauma to right hip is brought to emergency with complaints of sudden onset of dyspnea and dizziness.

Examination

Vitals:		Diaphoresis present
Pulse: 124 bpm	BP: 118/90 mm Hg	Right lower limb edema present extending from mid-thigh to foot
RR: 28/min	SpO_2: 84%	Calf muscle tenderness present

Investigations

ECG, CXR, 2D ECHO, D-dimer, pulmonary angiography

Management	
Supportive measures	Oxygen and IV fluids
Anticoagulation	**Unfractionated heparin:** 80 U/kg bolus → 18 U/kg/hr with aPTT monitoring. (Platelet count to be monitored at least every 3rd day) **LMWH:** Subcutaneously (should not be discontinued until INR is >2 for at least 24 hours) **Warfarin**: 5 mg/day—started on day 1 with INR monitoring Fondaparinux **Others:** Rivaroxaban, Apixaban, Argatroban, Ximelagatran *Note:* Anticoagulation to be continued for at least 6 months
Thrombolysis	Indication: Acute massive pulmonary embolism with cardiogenic shock. 100 mg rtPA IV infusion over 2 hours
Surgical therapy	Surgical embolectomy Caval filter

CASE 17: HEMOPTYSIS

History

A 40-year-old male chronic smoker, with past history of tuberculosis, presents with history of hemoptysis, 3 episodes in the last 1 day.

Examination

Vitals:
Pulse: 100 bpm BP: 100/60 mm Hg Clubbing +
Respiratory system: Coarse crepitations in right infraclavicular area

Investigations

Blood grouping, cross matching, CBC, PT/INR, CXR

Management

Measure vitals
Patient should be positioned upright or bleeding side down.
Secure airway—intubation with double lumen ET tube is preferable. Secure IV access: Large bore IV cannula
Administer IV fluids or blood transfusion, if needed Vasopressin 0.2 to 0.4 U/min IV
↓
Bronchoscopy

- Rigid bronchoscopy is preferable.
- Fiberoptic bronchoscopy may be used for cold saline lavage.
- Topical thrombin
- Laser photocoagulation
- Balloon catheter can be inflated proximally in the bleeding bronchus.

↓
Endovascular embolization
OR
Emergency surgery

CASE 18: HYPERTENSIVE EMERGENCY/CRISIS

Q. IM8.6 **Define, describe, discuss and recognize hypertensive urgency and emergency.**

Q. IM8.15 **Recognize, prioritize and manage hypertensive emergencies.**

History

A 69-year-old male patient presented with complaints of chest tightness and shortness of breath, k/c/o DM for the last 10 years and is a chronic smoker. History of hypertension, not on treatment.

Examination

Vitals: Pulse: 110 bpm BP: 230/120 mm Hg	**S/E:** CVS: S3 gallop, No murmur RS: Bi-basal fine inspiratory crackles

Management

Reduce the MAP by no more than 25% within minutes—2 hours. Continuous monitoring of BP

Labetalol	2 mg/min IV; maximum of 300 mg In acute renal failure, subarachnoid hemorrhage, intracranial bleed, and acute aortic dissection
Nitroglycerine	0.6–1.2 mg/hr IV In acute pulmonary edema, acute coronary syndrome, intracranial bleed
Sodium nitroprusside	0.3–1 µg/kg/min IV Drug of choice for hypertensive encephalopathy
Nicardipine	5 mg/hr IV titrate by 2.5 mg/hr at 5–15-minute intervals → Maximum 15 mg/hr
Esmolol	80–500 µg/kg over 1 minute → 50–300 µg/kg/min IV
Hydralazine	10–50 mg at 30 minute intervals

CASE 19: SEVERE DEHYDRATION

Q. PE27. 23 **Assess for signs of severe dehydration.**

History

A 23-year-old male, presented with history of vomiting 5–6 episodes/day and diarrhea 6–7 episodes/day for the last 2 days.

Clinical features

Sunken eyes, dry tongue, skin pinch going back slowly. BP is 80 mm Hg systolic.

Investigations

Electrolytes, urea, creatinine, RBS

Management

Secure IV access
Monitor vitals
I/O chartings
IV fluids started immediately—RL + 5% dextrose or normal saline
ORS can be given as soon as the patient is able to take orally (5 mL/kg/hr).
Reclassify dehydration and treat accordingly
Daily fluid requirement:

- Up to 10 kg: 100 mL/kg
- 10–20 kg: 50 mL/kg
- >20 kg: 20 mL/kg

	30 mL/kg	***70 mL/kg***
<12 months	1 hour	5 hours
>12 months	30 minutes	2.5 hours

CASE 20: CARDIAC ARREST

Immediate identification of cardiac arrest and activation of emergency response system

↓

Early CPR (30:2)

↓

Basic life support:
Circulation: Chest compression → push hard – push fast
Airway: Clear the airway—head tilt, chin lift; jaw thrust; sweep finger inside oral cavity; Heimlich maneuver
Breathing: Mouth to mouth

↓

Advanced cardiac life support:
Circulation: IV access, attach cardiac monitors, assess the rhythm and defibrillate
Airway: Face mask, Ambu bag, oropharyngeal airway, laryngeal mask airway, endotracheal tube
Breathing: Supplement oxygen

Drugs:
Adrenaline, vasopressin, amiodarone, magnesium sulfate, atropine

↓

Defibrillation:
Shockable rhythms are ventricular fibrillation and pulseless ventricular tachycardia

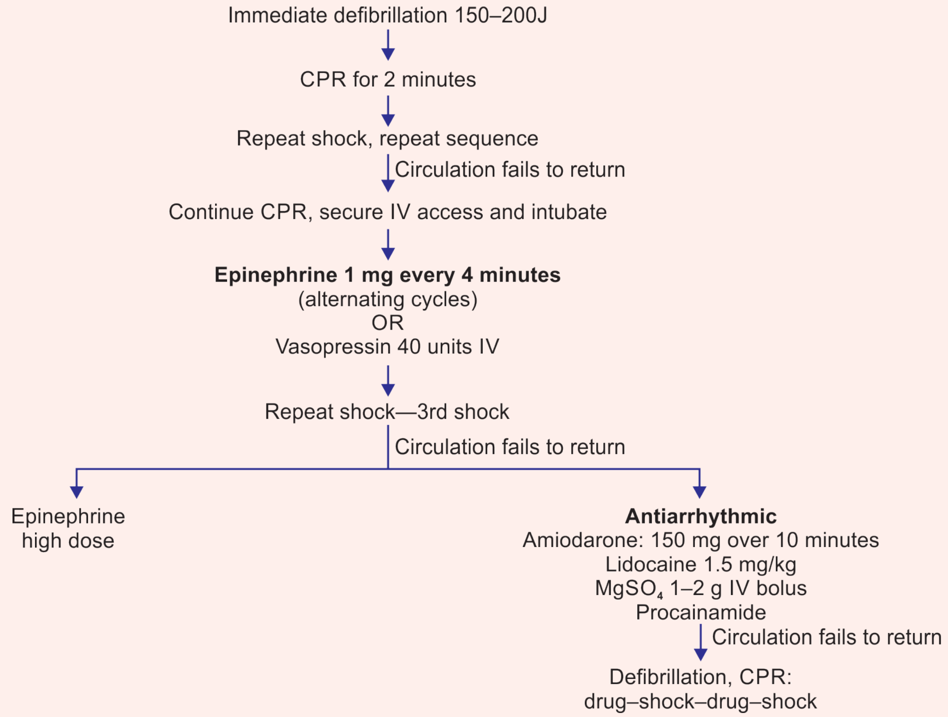
↓

Postresuscitation care:
Mild therapeutic hypothermia for resuscitated cardiac arrest victims who are hemodynamically stable but remain comatose

↓

Long-term management:
Identify and treat the cause
Example: Implantable cardioverter defibrillator in Brugada syndrome
Initiating antiarrhythmic

CASE 21: VENTRICULAR FIBRILLATION



Immediate defibrillation 150–200J

CPR for 2 minutes

Repeat shock, repeat sequence

Circulation fails to return

Continue CPR, secure IV access and intubate

Epinephrine 1 mg every 4 minutes
(alternating cycles)
OR
Vasopressin 40 units IV

Repeat shock—3rd shock

Circulation fails to return

Epinephrine
high dose

Antiarrhythmic
Amiodarone: 150 mg over 10 minutes
Lidocaine 1.5 mg/kg
$MgSO_4$ 1–2 g IV bolus
Procainamide

Circulation fails to return

Defibrillation, CPR:
drug–shock–drug–shock

CASE 22: UPPER GASTROINTESTINAL BLEED

History

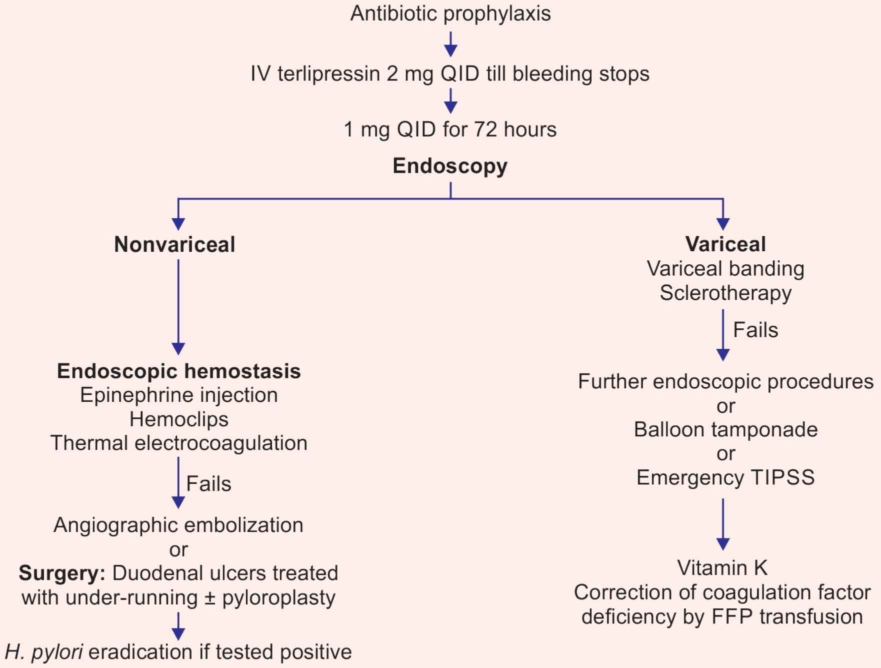
A 45-year-old male, k/c/o alcoholic liver disease, presents with 4 episodes of vomiting, fresh blood present.

Investigations

CBC, electrolytes, LFT, urea, PT/INR, blood grouping and cross-matching

Management

NPO
Secure IV access
Monitor vitals, I/O charting
Restore blood volume: IV fluids/blood transfusion if needed
IV PPI 80 mg bolus → 8 mg/hr infusion
Suspected variceal bleed



Antibiotic prophylaxis

IV terlipressin 2 mg QID till bleeding stops

1 mg QID for 72 hours

Endoscopy

Nonvariceal

Endoscopic hemostasis
Epinephrine injection
Hemoclips
Thermal electrocoagulation

Fails

Angiographic embolization
or
Surgery: Duodenal ulcers treated with under-running ± pyloroplasty

H. pylori eradication if tested positive

Variceal
Variceal banding
Sclerotherapy

Fails

Further endoscopic procedures
or
Balloon tamponade
or
Emergency TIPSS

Vitamin K
Correction of coagulation factor deficiency by FFP transfusion

CASE 23: MANAGEMENT OF ANGINA

Q. IM2.9 Distinguish and differentiate between stable and unstable angina and AMI-based on the clinical presentation.

History

A 58-year-old male patient, nonsmoker, diabetic, hypertensive with dyslipidemia presented with severe shortness of breath and chest tightness in the last 1 month. Pain is localized to the breastbone and does not radiate. It is aggravated while playing golf and subsides on rest.

Examination

Vitals:		**Cardiovascular system:** No abnormality detected
Temperature: 37°C	PR: 88 bpm	**Respiratory system:** No abnormality detected
BP: 162/80 mm Hg	RR: 24/min	**Per abdomen:** No abnormality detected

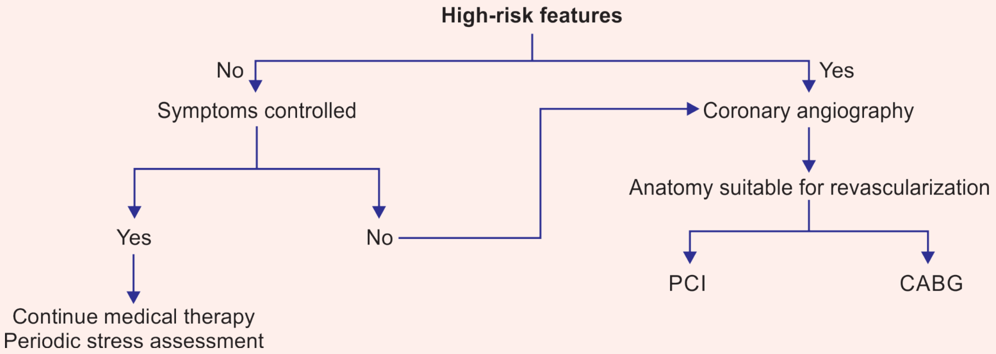
Management

Lifestyle modification	Limit salt intake to <5 g/day Smoking cessation Avoid simple carbohydrate	Increase PUFA consumption Limit alcohol intake Saturated fatty acids should be <10% of the total intake

Drug therapy

Nitrates	Glyceryl trinitrate 300–500 mg tablet or 400 mg meter dose inhaler Isosorbide dinitrate 10–20 mg TID
β-blockers (cardioselective)	Metoprolol 50–200 mg/day Bisoprolol 5–15 mg/day
Calcium channel blockers	**Dihydropyridines:** Nifedipine 5–20 mg TID, nicardipine **Non-DHP:** Verapamil 40–80 mg TID
Potassium channel activators	Nicorandil 10–30 mg BD
If channel antagonist	Ivabradine
Late sodium current blocker	Ranolazine

Aspirin 75–150 mg daily OR clopidogrel 75 mg daily.



CASE 24: ACUTE MYOCARDIAL INFARCTION

Q. PY5.6 Describe abnormal ECG in myocardial infarction.

Q. IM2.5 Define the various acute coronary syndromes and describe their evolution, natural history and outcomes.

Q. IM2.11 Order and interpret a chest X-ray and markers of acute myocardial infarction.

History

A 60-year-old male patient, k/c/o diabetes, was brought to casualty with complaints of single episode of sudden, rapid onset, severe chest pain, lasting more than 30 minutes, radiating to the medial aspect of his left arm associated with breathlessness, nausea, heavy perspiration, lightheadedness, fever, and cold clammy skin.

Examination

Vitals:

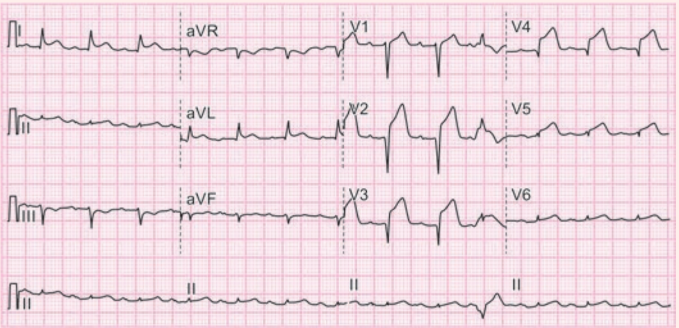
Pulse: 112 bpm	BP: 160/110 mm Hg	RR: 20/min	JVP: Normal

Cardiovascular system: S1 and S2 are heard, tachycardia

Investigations

12-Lead ECG showing acute anterolateral wall STEMI

Cardiac biomarkers: Troponin I, T, CKMB, bedside 2D ECHO



Management

Monitor vitals and oxygen saturation. Administer oxygen via mask or nasal cannula

Nitrates: Glyceryl trinitrate 300–500 µg sublingually
↓ If pain persists after 3 doses given 5 minutes apart
IV NTG 5–10 µg/min (maintain SBP >40 mm Hg)

Morphine: 2–5 mg IV—analgesia

Antiplatelets:
- Aspirin: 325 mg nonenteric formulations → 75–100 mg/day
- Clopidogrel: 300 mg orally → 75 mg/day
- Others: Oral—prasugrel, ticagrelor
- IV—abciximab, eptifibatide, tirofiban

Anticoagulants:
- Unfractionated heparin
- Low-molecular-weight heparin
- Direct thrombin inhibitor—bivalirudin
- Factor Xa inhibitor—fondaparinux

β-blockers unless contraindicated; ACEI; high dose statins

Specific treatment:
- **Thrombolytic therapy—**for ST elevation MI. Not recommended in unstable angina and NSTEMI
- **Coronary interventions—**percutaneous coronary interventions, coronary artery bypass graft

CASE 25: ORGANOPHOSPHATE POISONING

Q. FM9.5 Describe general principles and basic methodologies in treatment of poisoning: decontamination, supportive therapy, antidote therapy, procedures of enhanced elimination with regard to organophosphates and carbamates.

Q. PE14.3 Discuss the risk factors, clinical features, diagnosis and management of organophosphorus poisoning.

History

A 27-year-old male brought to casualty at 1:00 am with history of sudden loss of consciousness in his room after having a family quarrel. History of 4 episodes of vomiting and incontinence of urine and feces.

Examination

Vitals:
Temperature: 102°F
BP: 90/70 mm Hg
GCS: 7 (1, 2, 4)
Pulse: 100 bpm
RR: 28/min, shallow

Central nervous system:
Pupils: Bilateral pinpoint, nonreacting
Power: Grade I
Tone: Increased
Plantar: Nonelicitable
Per abdomen: Bowel sounds are exaggerated

Investigations

LFT, ABG, ECG, electrolytes, glucose, amylase

Management

Prevent further exposure—remove contaminate clothing, wash the skin thoroughly with soap and water, irrigate eyes
Airway cleared of excessive secretions → high flow oxygen
IV access → 0.9% NS infusion
Monitor vitals, SpO_2, auscultate the lungs. Ventilatory support, if needed
Gastric lavage with activated charcoal if the patient presents within 1 hour of ingestion, Foley catheterization

Atropine bolus	**Atropine infusion**
Start at 1.8–3 mg IV bolus; aim for HR > 80 bpm, SBP > 80 mm Hg and a clear chest If not achieved—double the dose every 5 minutes till there is satisfactory improvement	Start infusion at 20% of total dose of atropine required for atropinization Bronchorrhea is the most import sign for titrating the dose
Pralidoxime	Bolus: 30–45 mg/kg over 30 minutes followed by infusion: 8–12 mg/kg/hr Give PAM until atropine is no longer required
Benzodiazepines	Reduces agitation, seizures, fasciculations Sedation during ventilation

Intensive cardiorespiratory monitoring and support
Others: $MgSO_4$, $NaHCO_3$, clonidine, hemodialysis

CASE 26: MANAGEMENT OF ANAPHYLAXIS

History

A 12-year-old boy is brought to the emergency department after being stung by a bee. Initially complained of localized pain and swelling, but 15 minutes later he began to complain of shortness of breath, weakness, and dizziness.

Examination

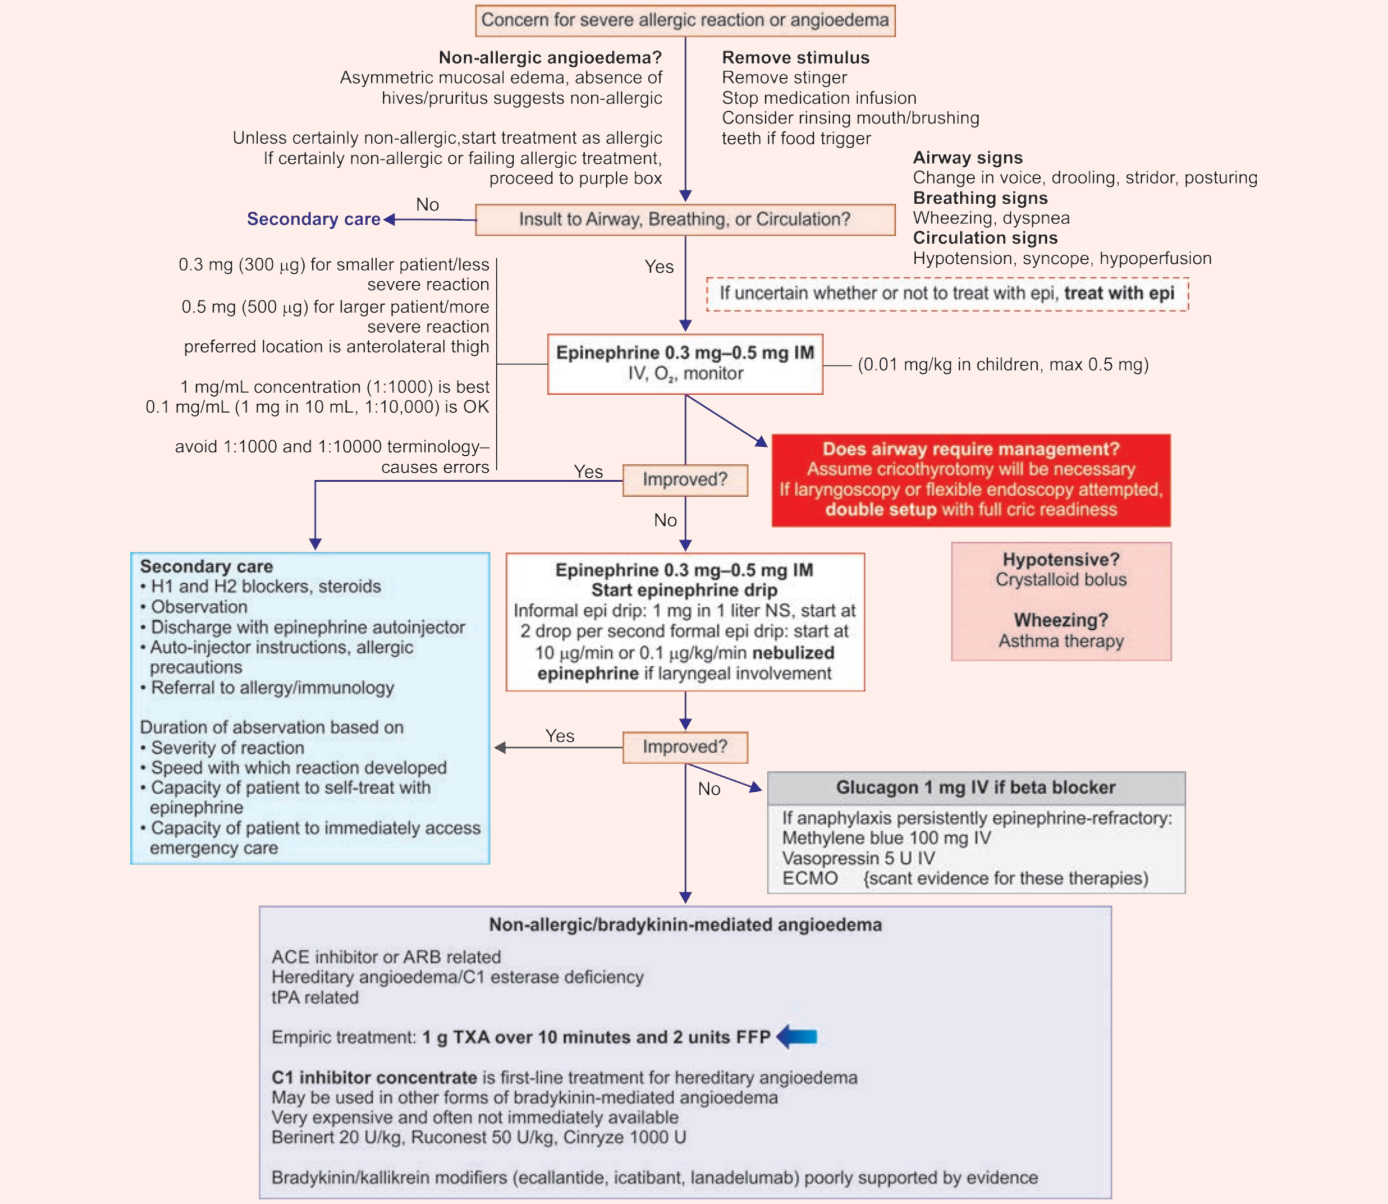
Vitals:
Pulse: 120 bpm
BP: 68/46 mm Hg
RR: 39/min

He has generalized urticaria
Respiratory system: Mild wheeze bilaterally
Cardiovascular system: Tachycardia present
Per abdomen: No abnormality detected

Management

Prevent further contact with the antigen
Ensure airway patency
Supportive measures:
- **Oxygen**
- IV fluids
- B_2 agonist

Drug therapy:
- **Adrenaline:** 0.01 mg/kg (maximum dose of 0.5 mg) per single dose. Injected intramuscularly into the mid-outer thigh (vastus lateralis muscle)
- **Antihistamines:**
  - Chlorphenamine—10 mg IM/slow IV
  - Diphenhydramine IM/IV
- **Corticosteroids:** Hydrocortisone 200 mg IV stat



Concern for severe allergic reaction or angioedema

Non-allergic angioedema?
Asymmetric mucosal edema, absence of hives/pruritus suggests non-allergic

Unless certainly non-allergic, start treatment as allergic
If certainly non-allergic or failing allergic treatment, proceed to purple box

Remove stimulus
Remove stinger
Stop medication infusion
Consider rinsing mouth/brushing teeth if food trigger

Airway signs
Change in voice, drooling, stridor, posturing
Breathing signs
Wheezing, dyspnea
Circulation signs
Hypotension, syncope, hypoperfusion

Insult to Airway, Breathing, or Circulation?

Secondary care

If uncertain whether or not to treat with epi, **treat with epi**

0.3 mg (300 µg) for smaller patient/less severe reaction
0.5 mg (500 µg) for larger patient/more severe reaction
preferred location is anterolateral thigh

1 mg/mL concentration (1:1000) is best
0.1 mg/mL (1 mg in 10 mL, 1:10,000) is OK

avoid 1:1000 and 1:10000 terminology–causes errors

Epinephrine 0.3 mg–0.5 mg IM
IV, O_2, monitor

(0.01 mg/kg in children, max 0.5 mg)

Does airway require management?
Assume cricothyrotomy will be necessary
If laryngoscopy or flexible endoscopy attempted, **double setup** with full cric readiness

Improved?

Secondary care
- H1 and H2 blockers, steroids
- Observation
- Discharge with epinephrine autoinjector
- Auto-injector instructions, allergic precautions
- Referral to allergy/immunology

Duration of observation based on
- Severity of reaction
- Speed with which reaction developed
- Capacity of patient to self-treat with epinephrine
- Capacity of patient to immediately access emergency care

Epinephrine 0.3 mg–0.5 mg IM
Start epinephrine drip
Informal epi drip: 1 mg in 1 liter NS, start at 2 drop per second formal epi drip: start at 10 µg/min or 0.1 µg/kg/min **nebulized epinephrine** if laryngeal involvement

Hypotensive?
Crystalloid bolus

Wheezing?
Asthma therapy

Improved?

Glucagon 1 mg IV if beta blocker

If anaphylaxis persistently epinephrine-refractory:
Methylene blue 100 mg IV
Vasopressin 5 U IV
ECMO {scant evidence for these therapies}

Non-allergic/bradykinin-mediated angioedema

ACE inhibitor or ARB related
Hereditary angioedema/C1 esterase deficiency
tPA related

Empiric treatment: **1 g TXA over 10 minutes and 2 units FFP**

C1 inhibitor concentrate is first-line treatment for hereditary angioedema
May be used in other forms of bradykinin-mediated angioedema
Very expensive and often not immediately available
Berinert 20 U/kg, Ruconest 50 U/kg, Cinryze 1000 U

Bradykinin/kallikrein modifiers (ecallantide, icatibant, lanadelumab) poorly supported by evidence

CASE 27: MANAGEMENT OF ACUTE SEVERE ASTHMA

Q. PE31.7 Develop a treatment plan for asthma appropriate to clinical presentation and severity.

History

A 16-year-old female patient complains of acute onset of difficulty in breathing. Symptoms increase on exposure to cold. Positive family history.

Examination

Vitals:

Pulse: 126 bpm	BP: 148/86 mm Hg	RR: 54/min	SpO_2: 88 at room air

Respiratory system: Expiratory wheeze noted

Investigations

ABG
PaO_2: Low due to hypoxia
$PaCO_2$: Low due to hyperventilation
Normal or rising $PaCO_2$ is a sign of impending respiratory failure

Management

Oxygen	***Bronchodilators***	***Systemic corticosteroids***	***Other***
High concentration (60%) **oxygen** via mask ventilation Maintain saturation >92%	**Nebulized salbutamol** 5 mg OR **Terbutaline** 2.5 mg to be administered immediately and repeated if required Can be followed up with **nebulized ipratropium bromide** 0.5 mg if required	**Hydrocortisone sodium succinate** 200 mg IV at presentation and repeated 4–6th hourly for 24 hours	**Aminophylline** IV infusion may be beneficial, but requires cardiac monitoring **$MgSO_4$**—IV bronchodilator **Antibiotics** are given only if there are signs of respiratory infection

Indications for assisted ventilation	Coma Respiratory arrest Deterioration in ABG—PaO_2 <60 mm Hg and falling, $PaCO_2$ >45 mm Hg and rising, pH <7.3 and falling Exhaustion, confusion, drowsiness

CASE 28: DIABETIC KETOACIDOSIS

Q. IM11.23 Describe the precipitating causes, pathophysiology, recognition, clinical features, diagnosis, stabilization and management of diabetic ketoacidosis.

History

A 32-year-old male patient, k/c/o type 1 diabetes mellitus, was taken to casualty with complaints of drowsiness, fever, diffuse abdominal pain and vomiting.

Examination

Patient appears confused. **Vitals:** Temperature: 39°C PR: 104 bpm BP: 100/70 mm Hg RR: 24/min	Dry mucous membranes	Poor skin turgor	Rales in right lower chest

Investigations

Arterial blood gas: pH: 7.12 pCO_2: 17 mm Hg HCO_3: 5.6 mEq/L **Urinalysis:** Glucose: 4^+ Ketone: 3^+	**Biochemistry:** Blood glucose: 420 mg/dL Blood urea nitrogen: 16 mg/dL Creatinine: 1.1 mg/dL **Electrolytes** Na: 139 mEq/dL Cl: 112 mEq/dL HCO_2: 11.2 mEq/L K: 5.0 mEq/dL

Management

Confirm the diagnosis
Monitor vitals and maintain hourly input/output monitoring
Send investigations—Na, K, HCO_3, phosphate, Mg, ABG, RFT
Monitor capillary glucose 1–2 hourly, electrolytes 4th hourly for the first 24 hours

Fluids	***Insulin***	***Potassium***
0.9% NS 10–20 mL/kg/hr 0.45% NS at 250–500 mL/hr **Replacement:** 1 L over 60 minutes followed by 1 L over 2 hours 1 L over 4 hours 1 L over next 4 hours 1 L over 6 hours Change over to 0.45% NS + 5% glucose when plasma glucose reaches 250 mg/dL	Short-acting insulin IV bolus 0.1 U/kg ↓ IV infusion at 0.1 U/kg/hr Increase 2–3-fold if no response by 2–4 hours Initiate subcutaneous insulin at least 2 hours prior to interruption of insulin infusion	**Serum potassium 3.5–5.2 mEq/L:** Replace with 10 mEq/hr or 20–30 mEq/L of infusion fluid **Serum potassium <3.5 mEq/L:** Replace with 40–80 mEq/hr. Do not administer insulin until potassium is corrected.

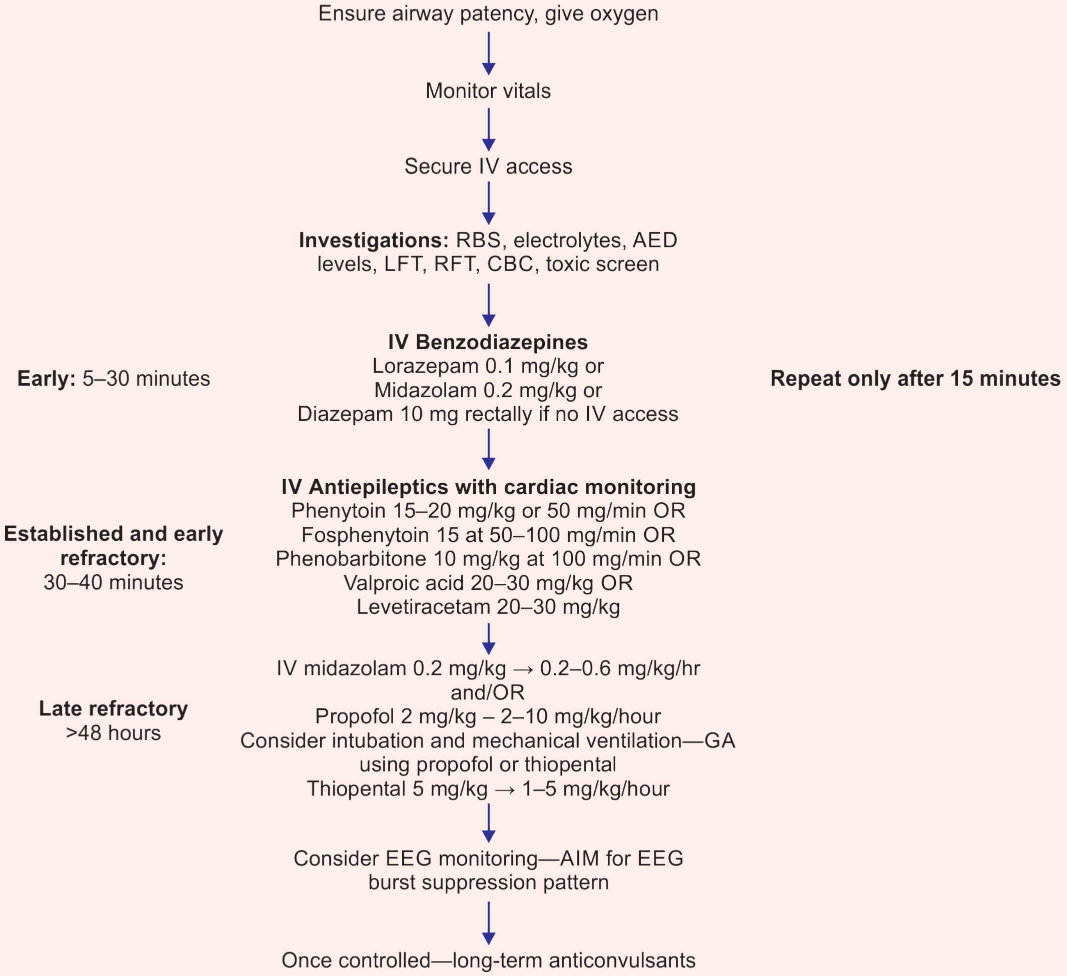
CASE 29: STATUS EPILEPTICUS

Q. PE27.6 Describe the etiopathogenesis, clinical approach and management of status epilepticus.

History

A 65-year-old male, k/c/o epilepsy, presents with a generalized tonic-clonic seizure for the last 30 minutes and loss of bladder control and difficulty in speech.

Management



Ensure airway patency, give oxygen

↓

Monitor vitals

↓

Secure IV access

↓

Investigations: RBS, electrolytes, AED levels, LFT, RFT, CBC, toxic screen

↓

Early: 5–30 minutes

IV Benzodiazepines
Lorazepam 0.1 mg/kg or
Midazolam 0.2 mg/kg or
Diazepam 10 mg rectally if no IV access

Repeat only after 15 minutes

↓

Established and early refractory:
30–40 minutes

IV Antiepileptics with cardiac monitoring
Phenytoin 15–20 mg/kg or 50 mg/min OR
Fosphenytoin 15 at 50–100 mg/min OR
Phenobarbitone 10 mg/kg at 100 mg/min OR
Valproic acid 20–30 mg/kg OR
Levetiracetam 20–30 mg/kg

↓

Late refractory
>48 hours

IV midazolam 0.2 mg/kg → 0.2–0.6 mg/kg/hr
and/OR
Propofol 2 mg/kg – 2–10 mg/kg/hour
Consider intubation and mechanical ventilation—GA using propofol or thiopental
Thiopental 5 mg/kg → 1–5 mg/kg/hour

↓

Consider EEG monitoring—AIM for EEG burst suppression pattern

↓

Once controlled—long-term anticonvulsants

CHAPTER

26

Environmental Diseases

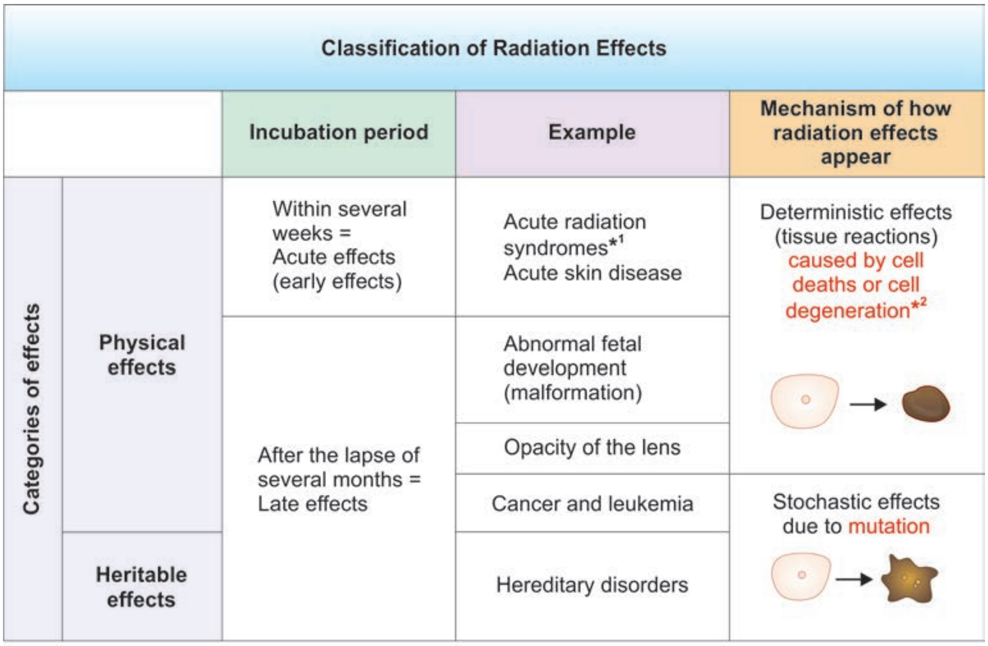
RADIATION EXPOSURE

Q. CM3.1 Describe the health hazards of radiation.

Types of Radiation

- **Ionizing radiation:** Used in X-rays, computed tomography (CT), radionuclide scans and radiotherapy. Radiations interact with atoms, and release energy and results in ionization which can cause molecular damage.
    - **Penetrating radiation:** It includes uncharged neutrons or high-energy electromagnetic radiations such as X-rays and gamma (γ) rays. It affects the skin and deeper tissues.
    - **Nonpenetrating radiation:** It includes charged subatomic alpha (α) and beta (β) particles.
- **Nonionizing radiations:** Ultraviolet (UV) rays of sunlight visible light, laser, infrared and microwave. It affects only skin. Nonionizing UV is used for therapy in skin diseases and laser therapy for diabetic retinopathy.
- **Sources:** Background radiation, medical exposure, industrial exposure, and accidental or deliberate nuclear events.

Effects of Radiation Exposure



Classification of Radiation Effects

		Incubation period	Example	Mechanism of how radiation effects appear
Categories of effects	Physical effects	Within several weeks = Acute effects (early effects)	Acute radiation syndromes^{*1} Acute skin disease	Deterministic effects (tissue reactions) caused by cell deaths or cell degeneration^{*2}
		After the lapse of several months = Late effects	Abnormal fetal development (malformation)	
			Opacity of the lens	
			Cancer and leukemia	Stochastic effects due to mutation
	Heritable effects		Hereditary disorders	

*1: Major symptoms are vomiting within several hours after exposure, diarrhea continuing for several days to several weeks, decrease of the number of blood cells, bleeding, hair loss, transient male sterility, etc.

*2: Deterministic effects do not appear unless having been exposed to radiation exceeding a certain dose level.

Q. Write short essay/note on effects of radiation exposure.

Radiation Sickness

Q. Write short note on radiation sickness.

- **Mild acute radiation sickness:** It is characterized by nausea, vomiting, and malaise following doses of about 1 Gy. Lymphopenia develops within several days, followed 2–3 weeks later by a reduction in all WBCs and platelets.
- **Acute radiation sickness:** It involves several systems and the extent of damage depends on the dose of radiation. Commonly involved systems are hematopoietic, GI, central nervous system, and skin.
- Effects on the individual are classified as either **deterministic or stochastic**.
  - ***Deterministic (threshold) effects****:* Deterministic effects (tissue reactions) are symptoms caused by deaths or degeneration of a number of cells constituting organs and tissues. Tissues with actively dividing cells (labile cells), such as bone marrow and GI mucosa, are more sensitive to ionizing radiation.
    - **Hemopoietic system:** Lymphocyte depletion is the most sensitive indicator of bone marrow injury. After exposure to a fatal dose, aplasia of the bone marrow is a most common cause of death.
    - **Gastrointestinal mucosal toxicity:** May cause death due to severe diarrhea, vomiting, dehydration, and sepsis.
    - **Gonads:** Highly radiosensitive and may cause temporary or permanent sterility.
    - **Eye:** Cataracts.
    - **Skin:** Radiation dermatitis (radiation burns) characterized by skin erythema, purpura, blistering, and secondary infection may occur. Complete loss of body hair develops after an exposure >5 Gy.
    - **Lung:** Acute inflammatory reactions and pulmonary fibrosis.
    - **Central nervous system syndrome:** Exposure of >30 Gy causes nausea, vomiting, disorientation, and coma. Death due to cerebral edema can follow within 36 hours. It may also cause **permanent neurological deficit.**
    - **Bone necrosis and lymphatic fibrosis** occur following regional irradiation, particularly for breast cancer.
    - **Thyroid gland** due to its capacity to concentrate iodine is responsible for its susceptibility to damage even after exposure to relatively low doses of radioactivity.
  - ***Stochastic effects:*** Stochastic (chance) effect is directly proportional to the dose of radiation. Stochastic effects are caused by mutation of cell genes, such as cancer and heritable effects
    - **Carcinogenesis:** It represents a stochastic effect. With acute exposures, leukemias (e.g., acute myeloid leukemia) may develop after a latent period of 2–5 years and solid tumors (e.g., skin, thyroid and salivary glands) after a latent period of about 10–20 years. Thereafter, the incidence of cancer increases with time. Cancer risk depends on the amount of radiation received, the time to accumulate the total dose and the interval following exposure.
    - **Teratogenic effects.**

Management of radiation exposure

- **Large-dose exposures:** Maintain adequate hydration, control of sepsis, and the management of marrow aplasia. Associated injuries such as thermal burns require treatment.
- **Internal exposure to radioisotopes:** White cell colony stimulation and hematopoietic stem cell transplantation may be required for marrow aplasia.
  - 137-cesium—chelation with Prussian blue
  - Radioactive iodine—supersaturated potassium iodide to block thyroid deposition
  - Plutonium, yttrium—chelation with diethylenetriaminepenta-acetic acid (DTPA)
  - Strontium—oral calcium or aluminum phosphate solutions can block absorption of strontium
- A cumulative risk of cancer following repeated imaging procedures has been well known and reduction of X-ray exposures should be made, whenever possible.
- **Hematopoietic toxicity:** Transfusion support for anemia and/or thrombocytopenia should utilize leukoreduced and irradiated or pathogen-reduced cellular blood products, whenever possible.
- **Cytokine support:** Administration of a myeloid cytokine (e.g., granulocyte colony-stimulating factor [G-CSF], granulocyte-macrophage colony-stimulating factor [GM-CSF])
- Romiplostim

HIGH ALTITUDE

Illnesses at High Altitude

- For normal individuals, ascent to altitudes up to 2,500 m or travel in a pressurized aircraft cabin is harmless.
- **Above 2,500 m** high-altitude illnesses may develop in **healthy individuals**, and **above 3,500 m** symptoms commonly develop.
- **Sudden ascent to altitudes above 6,000 m** (e.g., by aviators, balloonists and astronauts) may cause **decompression sickness**.
- The clinical features of decompression sickness are similar to in divers and even cause loss of consciousness.
- However, most high-altitude illness develops in travelers and mountaineers.

High-altitude Physiology

- **Hypobaric hypoxia**—pressure gradient as well as oxygenation decreases with increase in altitude.
- **Acclimatization—**complex physiological processes occurring in the body in response to acute hypobaric hypoxia; adaptation—different from acclimatization as it occurs in individuals living chronically in high-altitude areas.
- **Ventilation**—hypoxia stimulates peripheral chemoreceptors causing increase in minute ventilation called hypoxia ventilation response (HVR).
- **Arterial blood gases**—hyperventilation leads to decreased pCO_2 and increased pH—respiratory alkalosis. This is sensed by the central chemoreceptors and ventilation is inhibited.
- **Renal compensation**—within 24–48 hours, kidney starts excreting bicarbonate; therefore, decreasing pH so as to allow ventilation that leads to alkalosis.
- **Circulatory changes**—increased cardiac, pulmonary, and cerebral blood flow.
- **Hematological changes**—rise in Hb to increase oxygen carrying capacity of blood.

Q. Write short essay/note on mountain sickness.

Acute Mountain Sickness

- Acute mountain sickness (AMS) is a syndrome characterized by **headache, fatigue, anorexia, nausea, and vomiting, difficulty sleeping or dizziness**.
- Ataxia and peripheral edema may be present.
- **Etiology:** Not fully understood. Probably hypoxemia increases cerebral blood flow and intracranial pressure.
- **Symptoms:** Develop within 6–12 hours of an ascent and vary in severity from trivial to completely incapacitating.

Treatment of acute mountain sickness

- **Mild cases** require **rest and simple analgesics**.
- **Avoid further ascent, limit physical activity.**
- Symptoms usually resolve after 1–3 days at a stable altitude, but may recur with further ascent. Occasionally, it may then progress to cerebral edema.
- **Supplemental oxygen** may help.
- Dexamethasone: Dexamethasone 4 mg taken orally or intramuscularly, up to every six hours, for one to two days.
- **If the symptoms persist**, it indicates the need to descend but may respond to **acetazolamide** (carbonic anhydrase inhibitor) that produces a metabolic acidosis and stimulates ventilation. Acetazolamide is used as a prophylaxis, if a rapid ascent is planned.
- **Descent—**Effective treatment for AMS, but it is not mandatory or necessary except in the setting of intractable symptoms or suspicion that illness is progressing. Descent to an altitude lower than that where symptoms started effectively reverses AMS. Although the patient should descend as far as necessary for improvement, descending 500 to 1000 m is sufficient.

Chronic Mountain Sickness (Monge's Disease)

- It occurs on long exposure to high altitude.
- **Symptoms: Headache,** poor concentration, and signs of **polycythemia.**
- **Physical examination:** Cyanosis and clubbing of fingers.

High-altitude Cerebral Edema

- High-altitude cerebral edema (HACE) is a **rare, life-threatening** condition and usually preceded by AMS.
- **Symptoms: Ataxia and altered consciousness**. In addition to features of AMS, the patient also develops confusion, disorientation, visual disturbance, lethargy and can lead to loss of consciousness.
- **Signs: Papilledema and retinal hemorrhages** are common. Focal neurological signs may be detected.

Treatment

Requires immediate intervention.

Immediate descent at the first suspicion of HACE, while the victim is still ambulatory, is crucial to a favorable outcome.

Administered immediately upon the first suspicion of HACE (usually ataxia or change in consciousness) at an initial dose of 8–10 mg orally, intramuscularly, or intravenously (IV), followed by 4 mg every 6 hours until descent is achieved.

Sufficient oxygen should be given to maintain the oxygen saturation (SpO_2) above 90%.

High-altitude Pulmonary Edema

Q. Write short essay/note on high-altitude pulmonary edema.

- High-altitude pulmonary edema (HAPE) is a life-threatening condition.
- **Time of occurrence:** It usually occurs in the first 4 days after ascent above 2,500 m. Unlike HACE, HAPE may develop *de novo* without the preceding signs of AMS.
- **Types:** Classic HAPE—acute ascent in those residing at low altitude, re-entrant HAPE—acute ascent in those residing at high altitude after residing at low altitude.
- **Symptoms:**
  - Initially, **dry cough, exertional dyspnea** and **extreme fatigue**. Later, the cough becomes wet and may be with **blood-stained sputum**.
  - **Tachycardia** and **tachypnea** develop at rest. **Crepitations** may be heard in both lung fields. It may lead to severe hypoxemia, pulmonary hypertension.
- **Investigations:**
  - **Radiologically,** show **diffuse alveolar edema**.
  - Decreased arterial oxygen saturation.

Treatment of high-altitude pulmonary edema

- **Reversal of hypoxia** with **immediate descent** and **oxygen administration**.
- Rest and warmth.
- **Nifedipine** (20 mg four times daily) is given to reduce pulmonary arterial pressure. If there is delay in descent, oxygen therapy in a portable pressurized bag should be given.
- **Other treatment options:** Hyperbaric therapy, positive airway pressure, tadalafil/sildenafil, dexamethasone, salmeterol.

High-altitude Retinal Hemorrhage

- It may be found in about **30% of trekkers** at 5,000 m and is **usually asymptomatic** and **resolve spontaneously**.
- **Visual defects** can develop when the hemorrhage involves the macula.
- There is **no specific treatment**.

Venous Thrombosis

- Can develop at **altitudes over 6,000 m**.
- **Risk factors** are dehydration, inactivity, cold and use of oral contraceptive pill at high altitude.

Refractory Cough

- **Cough** is common at high altitude and usually benign.
- Causes include **breathing of dry, cold air** and **increased mouth breathing**.
- It may be similar to cough that occurs in early HAPE.

HEAT-RELATED ILLNESS

Q. Discuss clinical features of hyperthermia.

Hyperthermia

- **Definition:** Hyperthermia is defined as an **elevation of the core body temperature** above the normal diurnal range of 36–37.5°C due **to failure of thermoregulation**.
- A **temperature above 40°C** (or 104°F) is generally considered as **severe hyperthermia**. Heat-related illnesses are listed in **Box 26.1**.

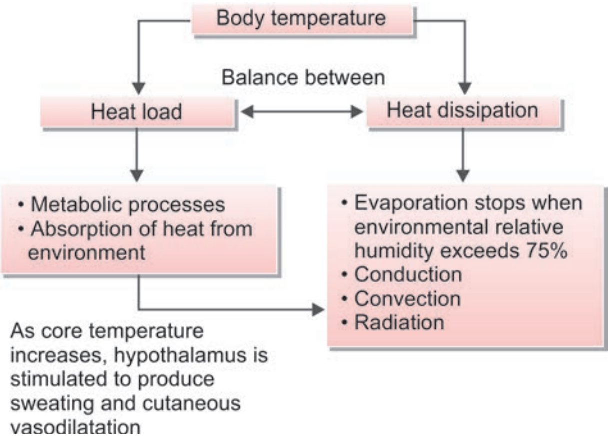
Box 26.1: Heat-related illnesses.

- Heat cramps
- Heat edema
- Heat exhaustion
- Exertional heat injury
- Heatstroke

Pathophysiology (Flowchart 26.1)

- Temperature elevation is accompanied by an increase in oxygen consumption and metabolic rate, resulting in hyperpnea and tachycardia.
- Above 42°C (108°F), oxidative phosphorylation becomes uncoupled, and a variety of enzymes cease to function.
- A cytokine-mediated systemic inflammatory response develops, and production of heat shock proteins is increased.
- Blood is shunted from the splanchnic circulation to the skin and muscles, resulting in GI ischemia and increased permeability of the intestinal mucosa.
- Hepatocytes, vascular endothelium, and neural tissue are most sensitive to increased core temperatures, but all organs may ultimately be involved.
- In severe cases, patients develop multiorgan system failure and disseminated intravascular coagulation (DIC).

FLOWCHART 26.1: Pathophysiology.



Body temperature
Balance between
Heat load
Heat dissipation
• Metabolic processes
• Absorption of heat from environment
• Evaporation stops when environmental relative humidity exceeds 75%
• Conduction
• Convection
• Radiation
As core temperature increases, hypothalamus is stimulated to produce sweating and cutaneous vasodilatation

Heatstroke

Q. Write short essay/note on heatstroke.

Types of Heatstroke

- **Classic/Nonexertional**
  - "Summer Heat Waves"
  - No sweat in 84–100% of patients
  - More insidious onset
  - Usually affects elderly and debilitated patients with chronic underlying disease
  - Rhabdomyolysis and acute renal failure (ARF) rare.
- **Exertional**
  - Young, healthy, laborers, athletes, military recruits who over **exert themselves in high ambient** (temperatures or in a hot environment) to which they are **not acclimatized**.
  - Rhabdomyolysis and ARF common.
  - Usually have predisposing factor.

Predisposing Factors

- **Increased heat production:** Hyperthyroidism, exercise, sepsis.
- **Impaired heat loss** (impaired sweating)
  - **Drugs:** Anticholinergics, anti-Parkinsonian drugs, antihistamines, butyrophenones, phenothiazines, tricyclics.
  - **Abnormal sweat glands:** Examples: (1) sweat gland injury following acute heatstroke, barbiturate poisoning; (2) cystic fibrosis; and (3) healed thermal burn.
  - **Salt and water depletion:** Diuretic induced.
  - Hypokalemia

- **Impaired voluntary mechanisms**: Coma, physical disability, mental illness
- **Impaired delivery of blood to peripheral circulation:** Cardiovascular disease, hypokalemia (decreased muscle blood flow), dehydration.
- **Others:** Elderly, high ambient temperature and humidity, poor ventilation, lack of acclimatization, obesity, fatigue, diabetes mellitus, malnutrition, and alcoholism.

Clinical Features

- It may develop without any warning prodrome prior to development of nonexertional heatstroke (classic heatstroke).
- As thermoregulatory mechanisms fail **body temperature rises rapidly** and patient can **deteriorate rapidly** from apparent baseline health to coma or mentally dull state.
- **Three cardinal signs are:**
  - **CNS dysfunction**
  - **Hyperpyrexia** (core temperature >40°C)
  - **Hot dry skin**: Pink or ashen depending on circulatory state. However, it may be clammy and sweat.

  Clinical features of heat exhaustion and heatstroke are depicted in **Figure 26.1**.

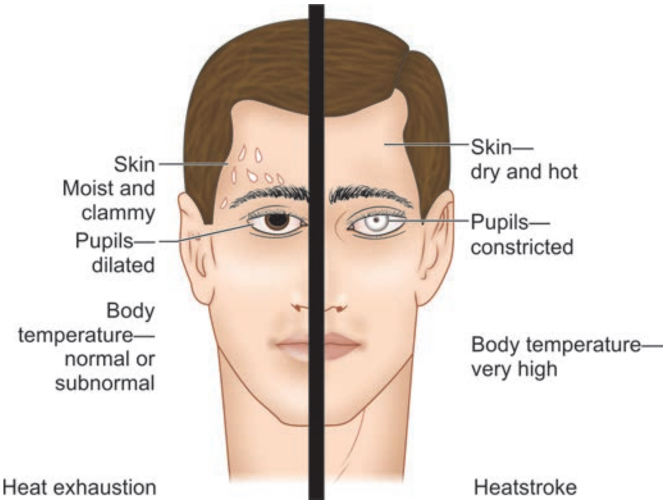


FIG. 26.1: Clinical features of heat exhaustion and heatstroke.

- **Central nervous system**
  - **Direct thermal toxicity** causes cell death, cerebral edema, and local hemorrhage. Irritability or irrational behavior may precede the development of either form of heatstroke.
  - **Confusion, aggressive behavior, delirium, convulsions,** and pupillary abnormalities may progress rapidly to coma.
  - ± decorticate posturing, fecal incontinence, flaccidity or hemiplegia (however, focal signs are unusual).
  - **Cerebellar signs**, including **ataxia and dysarthria**
  - **Hypothalamic damage** may exacerbate heatstroke by further impairing sweating and heat loss.
  - Lumbar puncture may show increased protein, xanthochromia, and slight increase in lymphocytes.
- **Cardiovascular system**
  - **Tachycardia, dysrhythmias**
  - Hypotension or normotensive with wide pulse pressure.
  - Hyperdynamic-hemodynamic profile.
  - **Myocardial pump failure:** Myocardial damage and frank infarction frequent even in patients with normal coronaries due to the effect of heat on myocytes and coronary hypoperfusion secondary to hypovolemia.
- **Respiratory system**
  - **Extreme tachypnea** with respiratory rate up to 60/minute.
  - Crackles and cyanosis—signs of **pulmonary edema**.
  - Direct thermal injury to pulmonary vascular endothelium may lead to cor pulmonale or **acute respiratory distress syndrome (ARDS).**
- **Metabolic**
  - Dehydration leading to raised urea and creatinine, and hemoconcentration.
  - Sweating results in **low levels of Na, Mg, K**, during early phase of the illness.
  - **Rhabdomyolysis** resulting in hyperkalemia, hypocalcemia, and renal failure.
  - **Metabolic acidosis and respiratory alkalosis common.**
- **Splanchnic**
  - Ischemic intestinal ulceration common. May lead to hemorrhage.
  - Hepatic damage common. In 5–10%, hepatic necrosis may be severe enough to cause death.
- **Renal**
  - As a direct result of heat potentiated by dehydration and **rhabdomyolysis**.
  - **Acute renal failure** 5–6 times more common in patients with exertional heatstroke in whom it occurs in 30–35%.

Box 26.2: Investigations in heatstroke.

- Temperature recording
- Electrolytes, urea, creatinine, calcium
- Liver function tests
- Creatine phosphokinase (CPK)
- Arterial blood gas (ABG)
- ECG monitoring
- Urine output
- Full blood count (FBC), clotting tests, fibrinogen, FDP, D-dimer: Anemia frequent, platelets low/normal, lymphocytosis
- Test urine for myoglobin

Box 26.3: Differential diagnosis of heatstroke.

- Acute CNS infection
- Cocaine, amphetamine, antihistamine overdosage
- Cerebral malaria
- Severe sepsis
- Thyroid storm
- Drug toxicity
- Neuroleptic malignant syndrome
- Serotonin syndrome

Box 26.4: Various cooling methods that can be carried out in heatstroke.

- Evaporative
- Immersion
- Strategic ice packs
- Ice cold IV fluids
- Ice packing
- Cooling blankets
- Gastric lavage
- Peritoneal lavage
- Cardiac bypass
- Endovascular cooling
- Catheters

- **Hematological**
  - **Anemia and bleeding:** Result from direct inactivation of platelets and clotting factors by heat, liver failure, and platelet aggregation due to heat.
  - **Disseminated intravascular coagulation:** Due to activation of clotting cascade by damaged vascular endothelium. Latter may be damaged as a direct result of heat.

Investigations

See **Box 26.2**.

Management

- The most important causes of severe hyperthermia [>40°C (104°F)] due to a **failure of thermoregulation** are **heatstroke, neuroleptic malignant syndrome (NMS), and malignant hyperthermia** [Other differentials refer **(Box 26.3)**].
- The context in which symptoms develop usually suggests the etiology (e.g., exertional heatstroke following exercise in high ambient temperature and humidity; malignant hyperthermia after anesthetic agents; NMS among patients treated with antipsychotic medications).
- **First aid for heatstroke or sunstroke**
  - Remove victim to cooler location, out of the sun.
  - Loosen or remove clothing, and if possible, immerse the victim in very cool water.
  - If immersion cannot be done, cool victim with water, or wrap in wet sheets and fan to facilitate quick evaporation.
  - Use cold compresses mainly in the region of the head and neck, armpits and groin.
  - Seek medical attention immediately—continue first aid to lower temperature. Until medical help takes over.
  - Not to administer any medication to lower fever because it is not useful and may be in fact cause more harm.
  - Do not use an alcohol rub.
  - Do not give anything by mouth including water until the condition has been stabilized.
- **In hospital care:** Usually treat the heatstroke in a critical care unit. Various cooling methods are listed in **Box 26.4**.
- **Supportive**
  - **IV volume replacement.**
  - If inotrope required dobutamine probably drug of choice.
  - **Urgent treatment of hyperkalemia.**
  - **Do not treat hypocalcemia per se;** only give calcium, if ECG changes of severe hyperkalemia occur as calcium may exacerbate rhabdomyolysis.
  - Small dose of mannitol may benefit patients with rhabdomyolysis, intravenous lorazepam for shivering.

- **Avoid following medications**
  - **Acetylsalicylic acid (ASA):** Uncouples oxidative phosphorylation and increases temperature.
  - **Paracetamol:** Increases hepatic dysfunction and may create toxicity.
  - **Dantrolene** is not effective, but good for malignant hyperthermia.

Hypothermia

Q. PE27.24 **Define hypothermia. Describe the clinical features, complications and management of hypothermia.**

- **Definition:** Hypothermia is defined as a core temperature below 35°C (95°F).
  - **Mild hypothermia:** Core temperature 32–35°C (90– 95°F).
  - **Moderate hypothermia:** Core temperature 28–32°C (82–90°F).
  - **Severe hypothermia:** Core temperature below 28°C (82°F).
- Primary hypothermia happens because of overwhelming cold exposure. Heat production in itself is normal.
- **Secondary hypothermia:** Hypothyroidism, Addison's disease, malnutrition, burns, hypothalamic abnormalities, sepsis, thiamine deficiency, alcohol intoxication, hypoglycemia, etc.

Clinical Symptoms (Table 26.1)

TABLE 26.1: Clinical symptoms of hypothermia (HT).

Stage	*Features*
Mild (HT I)	Normal mental status with shivering. Estimated core temperature 32–35°C (90–95°F) ➢ Increased metabolic rate ➢ Maximum shivering thermogenesis, "cold diuresis" ➢ Amnesia/dysarthria/ataxia ➢ Loss of coordination ➢ Tachycardic, tachypneic
Moderate (HT II)	Altered mental status without shivering. Estimated core temperature 28–32°C (82–90°F) ➢ Stupor ➢ No shivering ➢ Bradycardic/atrial fibrillation ➢ Decreased BP and RR ➢ Pupils dilated (<30°C)
Severe (HT III)	Unconscious Estimated core temperature 24–28°C (75–82°F)
Severe (HT IV)	Apparent death. Core temperature 13.7–24°C (56.7– 75°F) (resuscitation may be possible) ➢ Coma ➢ No corneal or oculocephalic reflexes ➢ Decreased BP ➢ Ventricular fibrillation (maximum risk: 22°C) ➢ Apnea ➢ Asystole ➢ Areflexia/fixed pupils ➢ Flat EEG (19°C)
Death (HT V)	Due to irreversible hypothermia. Core temperature <9–13.7°C (48.2–56.7°F) (resuscitation not possible).

Investigations

- These include: Routine blood investigations, X-ray chest, and ECG.
- **Electrocardiographic changes**
  - Hypothermia causes characteristic ECG changes because of slowed impulse conduction through potassium channels. This results in prolongation of all the ECG intervals, including RR, PR, QRS, and QT.
  - Elevation of the J point (only if the ST segment is unaltered), producing a characteristic **J or Osborn wave (Fig. 26.2)**. The height of the Osborn wave is roughly proportional to the degree of hypothermia.

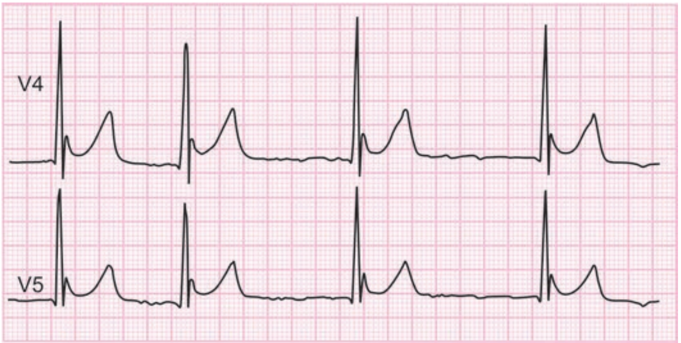

FIG. 26.2: ECG of Osborn wave.

Management

- **Evaluation and support of the airway, breathing, and circulation**.
- **Prevention of further heat loss**.
- **Initiation of rewarming** appropriate to the degree of hypothermia. Various rewarming methods are:
  - **Passive rewarming:**
    - **Endogenous heat production:** Shivering, metabolic rate, TSH, sympathetic activity.
    - Involves decreasing heat loss—remove from cold environment, remove wet clothes, provide blanket.
  - **Active external rewarming and active internal (core) rewarming (Table 26.2)**
- **Treatment of complications:** Careful attention to potential complications, including hypotension during active rewarming, arrhythmia, hyperkalemia, hypoglycemia, rhabdomyolysis, bladder atony, and bleeding diathesis.

TABLE 26.2: Methods of active external rewarming and active internal (core) rewarming.

Active external rewarming	*Active internal (core) rewarming*
➢ Heat to body surfaces ➢ Heating blankets (fluid-filled) ➢ Air blankets ➢ Radiant warmers ➢ Immersion in hot bath ➢ Water bottles/heating pads ➢ Less effective than internal rewarming, if vasoconstricted. Concern about after drop. ➢ *Rewarming rates:* 1–2.5°C/h	➢ Warm IV fluids ➢ Warm, humid oxygen ➢ Peritoneal lavage ➢ Gastric/esophageal lavage ➢ Bladder/rectal lavage ➢ Pleural/mediastinal lavage ➢ Microwaves (diathermy) ➢ Extracorporeal circulatory rewarming

DROWNING (SUBMERSION INJURIES)

Q. Write a short essay on near drowning in fresh water.

- **Drowning:** Asphyxiation caused by submersion in a liquid that causes interruption of the body's oxygen absorption.
- **Secondary drowning (and near-drowning)** is one of the post-immersion respiratory syndromes. It is defined as deterioration of pulmonary function that follows deficient gas exchange due to loss or inactivation of surfactant.
- **Salt versus fresh water drowning** is no longer emphasized as degree of pulmonary insult is determined by quantity aspirated.
- **Wet drowning:** Aspiration of water into airways and lungs (85%). 1–3 cc of aspirated water will lead to destruction of surfactant, alveolar instability, noncardiogenic pulmonary edema, and impaired gas exchange.
- **Dry drowning:** Severe parasympathetically mediated laryngospasm (15%).
- Aspiration of >11 mL/kg of body weight must occur before blood volume changes occur, and >22 mL/kg before electrolyte changes take place.
- It is unusual for nonfatal drowning victims to aspirate >3–4 mL/kg.
- Both types result in common pathway of hypoxia which leads to acidosis, cardiac arrest, and brain death.

Pathophysiology of Drowning

Risk Factors for Drowning (Box 26.5)

Three peaks in incidence:

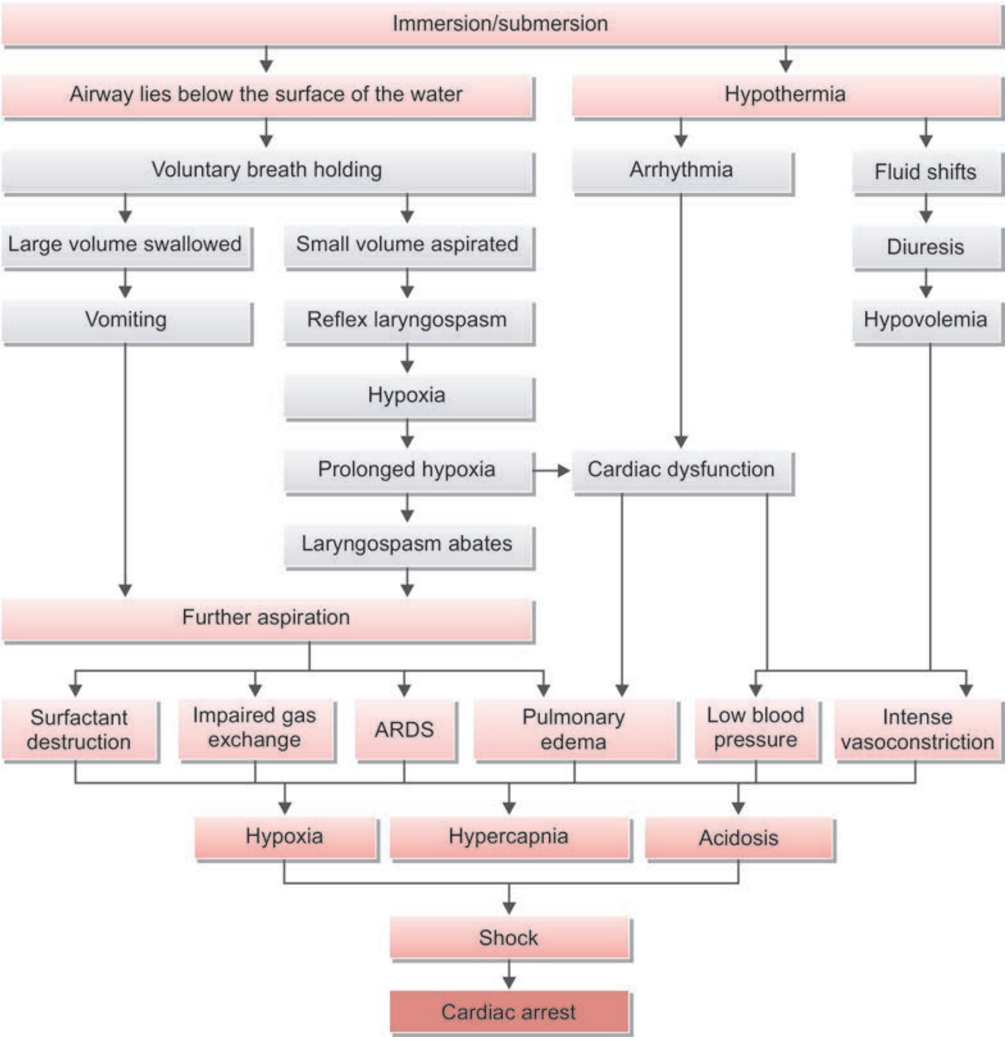
1. Toddlers
2. Adolescents
3. Elderly

Various stages of drowning are shown in **Flowchart 26.2**.

Box 26.5: Risk factors for drowning.

- Drug and alcohol intoxication
- Cardiac arrest
- Hypoglycemia
- Seizure
- Suicidal or homicidal behavior
- Child abuse
- Inadequate adult supervision
- Inability to swim or overestimation of swimming capabilities
- Risk-taking behavior
- Hypothermia, which can lead to rapid exhaustion or cardiac arrhythmias
- Undetected primary cardiac arrhythmia: Cold water immersion and exercise can cause fatal arrhythmias in patients with the congenital long QT syndrome type 1. Similarly, mutations in the cardiac ryanodine receptor (RyR)-2 gene, which is associated with familial polymorphic VT in the absence of structural heart disease or QT prolongation, have been identified in some individuals with unexplained drowning.
- Hyperventilation prior to a shallow dive: Swimmers commonly hyperventilate in order to prolong the duration of underwater swimming, and by so doing they reduce the arterial partial pressure of carbon dioxide ($PaCO_2$) while the content of oxygen (CaO_2) does not increase appreciably. As the individual swims, oxygen is consumed and the partial pressure of oxygen (PaO_2) falls to 30–40 mm Hg before the $PaCO_2$ rises sufficiently to trigger the urge to breathe. This can lead to cerebral hypoxia, seizures, and loss of consciousness, which can result in drowning.

FLOWCHART 26.2: Pathophysiology of drowning.



Immersion/submersion
Airway lies below the surface of the water
Hypothermia
Voluntary breath holding
Arrhythmia
Fluid shifts
Large volume swallowed
Small volume aspirated
Diuresis
Vomiting
Reflex laryngospasm
Hypovolemia
Hypoxia
Prolonged hypoxia
Cardiac dysfunction
Laryngospasm abates
Further aspiration
Surfactant destruction
Impaired gas exchange
ARDS
Pulmonary edema
Low blood pressure
Intense vasoconstriction
Hypoxia
Hypercapnia
Acidosis
Shock
Cardiac arrest

Signs and Symptoms

- About 70% of patients develops signs within 7 hours.
- Alertness, agitation, coma.
- Cyanosis, coughing, and pink frothy sputum (pulmonary edema).
- Tachypnea, tachycardia.
- Low-grade fever.
- Rales, rhonchi, and less often wheezes.
- Signs of associated trauma to the head and neck should be sought.
- Persons with hypothermia can have significant hypovolemia and hypotension due to a “cold diuresis”. This occurs because during the early phase of vasoconstriction, blood moves to the core, causing central volume receptors to sense fluid overload, and resulting in decreased antidiuretic hormone production.
- **End organ effects:**
  - **Pulmonary:** Fluid aspiration results in varying degrees of hypoxemia, noncardiogenic pulmonary edema—ARDS.
  - **Neurologic:** Hypoxemia and ischemia cause neuronal damage, which can produce cerebral edema and elevations in intracranial pressure which can progress into hypoxic ischemic encephalopathy.
  - **Cardiovascular:** Arrhythmias secondary to hypothermia and hypoxemia like sinus tachycardia, sinus bradycardia, and atrial fibrillation.

- **Acid-base and electrolytes:** A metabolic and/or respiratory acidosis is often observed. Rarely drowning in concentrated seawater can produce life-threatening hypernatremia, hypermagnesemia, and hypercalcemia due to absorption of swallowed seawater.
- **Renal:** Renal failure due to acute tubular necrosis resulting from hypoxemia, shock, hemoglobinuria, or myoglobinuria is rare.

Poor prognostic signs of drowning are listed in **Box 26.6**.

Box 26.6: Poor prognostic signs of drowning.

- Duration of submersion >5 minutes (most critical factor)
- Time to effective basic life support >10 minutes
- Resuscitation duration >25 minutes
- Glasgow coma scale <5 (i.e., comatose)
- Persistent apnea and requirement of cardiopulmonary resuscitation in the emergency department
- Arterial blood pH <7.1 upon presentation

Management

- It includes prehospital care, emergency department (ED) care, and inpatient care.
- **Ventilation is the most important** initial treatment of submersion injury.
- The Heimlich maneuver or other postural drainage techniques to remove water from the lungs are of no proven value, and rescue breathing should not be delayed in order to perform these maneuvers.
- Standard CPR protocol needs to be followed.
- Identify spine injuries and other major organ injuries and manage accordingly.
- *Supportive care:* Renal failure, shock, infections, etc.
- Empirical antibiotics to cover pulmonary infections.

Appendix

LABORATORY VALUES OF CLINICAL IMPORTANCE

In this appendix, tables of reference values of some important common laboratory investigations are provided which will help in interpreting the results during examinations as well as during clinician's practice. The term "reference values" has replaced older terminology "normal values/ranges". A variety of factors can influence reference values and it varies between laboratories depending on the laboratory methods, mode of standardization, and other factors. This is especially the case with enzyme assays. The reference or "normal" ranges given in this appendix may, therefore, not be appropriate for all laboratories and they should only be used as general guidelines. Hence, reference values provided by the laboratory performing the test should be used in the interpretation of laboratory results. Most clinical laboratories and all medical and scientific journals use SI system. Since, conventional units are still used in many laboratories of developing countries, in this section, laboratory values are given in both conventional and international units. Many analytes are measured in either serum (the supernatant of clotted blood) or plasma (the supernatant of anticoagulated blood).

The laboratory reference values in this appendix is divided into different section namely: (1) hematology and coagulation (**Table A1.1**), (2) clinical chemistry of blood (**Table A1.2**), (3) lipid profile (**Table A1.3**), (4) urea and electrolytes (**Table A1.4**), (5) thyroid function tests (**Table A1.5**), (6) urine (**Table A1.6**), (7) cerebrospinal fluid (**Table A1.7**), and short list of routinely used formulas in medicine (**Table A1.8**).

Hematology and Coagulation (Table A1.1)

TABLE A1.1: Hematology and coagulation.

Component (specimen)	*Reference value*	
	Conventional	*SI units*
RBCs and hemoglobin		
RBC count		
➢ Males	4.5–5.5 × 10^{12}/L (mean 5.0 × 10^{12}/L)	
➢ Females	3.8–4.8 × 10^{12}/L (mean 4.3 × 10^{12}/L)	
RBC diameter	6.7–7.7 µm (mean 7.2 µm)	
RBC indices (absolute values)		
➢ Mean corpuscular volume (MCV)	82–100 fL	
➢ Mean corpuscular hemoglobin (MCH)	27–32 pg	
➢ Mean corpuscular hemoglobin concentration (MCHC)	31–35 g/dL	
➢ Red cell distribution width (RDW)	11.5–14.0%	
RBC lifespan	120 days	
Erythrocyte sedimentation rate (ESR) (Whole blood)		
➢ Westergren, 1st hour		
– Males	0–15 mm 1st hour	
– Females	0–20 mm 1st hour	
– Children	0–10 mm 1st hour	
➢ Wintrobe, 1st hour		
– Males	0–9 mm 1st hour	
– Females	0–20 mm 1st hour

Contd...

	Reference value	
Component (specimen)	***Conventional***	***SI units***
Ferritin (serum)		
➢ Males	20–300 ng/mL	20–300 µg/L
➢ Females	15–200 ng/mL	15–200 µg/L
Folate (serum)	3–20 µg/L	3–20 ng/mL
Hematocrit (PCV)		
➢ Males	38–47%	
➢ Females	36–46%	
➢ Neonate (cord blood)	45–70%	
Hemoglobin (Hb)		
➢ Adult hemoglobin (HbA)	95–98%	
➢ Males	13.0–17.0 g/dL	
➢ Females	12.0–15.0 g/dL	
➢ Hemoglobin A_2 (HbA_2)	1.5–3.5%	
➢ Hemoglobin, fetal (HbF) in adults	<0–2%	
➢ HbF, children under 6 months	<5%	
➢ Iron, total (serum)	80–180 µg/dL	7–25 µmol/L
➢ Total iron binding capacity (TIBC)	250–425 µg/dL	45–73 µmol/L
➢ Transferrin saturation	20–45%	0.20–0.45
Osmotic fragility		
➢ Slight hemolysis	at 0.45–0.39 g/dL NaCl	
➢ Complete hemolysis	at 0.33–0.36 g/dL NaCl	
➢ Mean corpuscular fragility	0.4–0.45 g/dL NaCl	
Reticulocytes		
➢ Adults	0.5–2.5%	
➢ Infants	2–6%	
➢ Newborn (cord blood)	1–7%	
Transferrin saturation		
➢ Male	25–56%	
➢ Female	14–51%	
Vitamin B_{12} (serum)		
➢ Body stores	10–12 mg 2–3 µg	
➢ Daily requirement	280–1,000 pg/mL	
➢ Serum level		
Autohemolysis test (whole blood)	0.4–4.50%	0.004–0.045
Autohemolysis test with glucose (whole blood)	0.3–0.7%	0.003–0.007
Leukocytes		
Differential leukocyte count (DLC)		
➢ P (polymorphs or neutrophils)	40–70% (2,000–7,500/µL)	
➢ L (lymphocytes)	20–40% (1,500–4,000/µL)	
➢ M (monocytes)	2–10% (200–800/µL)	
➢ E (eosinophils)	1–6% (40–450/µL)	
➢ B (basophils)	<1% (10–100/µL)	
Total leukocyte count (TLC)		
➢ Adults	4,000–11,000/µL	
➢ Infants (full term, at birth)	10,000–25,000/µL	
➢ Infants (1 year)	6,000–16,000/µL	
Platelets and coagulation		
Bleeding time (BT)		
➢ Ivy's method	2–7 minutes	
➢ Template method	2–9 minutes	
Clot retraction time (clotted blood)		
➢ Qualitative	Visible in 60 minutes (complete in <24 hours)	
➢ Quantitative	48–64% (55%)	
Clotting time (CT)		
➢ Lee and White method	4–11 minutes	
D-dimer (plasma)	220–740 ng/mL	
Fibrinogen (plasma)	200–400 mg/dL

Lipid Profile (Table A1.3)

TABLE A1.3: Lipid profile.

	Reference value	
Component	***Conventional***	***SI units***
Total serum cholesterol		
➢ Desirable for adults	<200 mg/dL	<5.17 mmol/L
➢ Borderline high	200–239 mg/dL	5.17–6.18 mmol/L
➢ High undesirable	>240 mg/dL	>6.21 mmol/L
LDL cholesterol		
➢ Desirable range	100–130 mg/dL	<3.34 mmol/L
➢ Borderline high	130–159 mg/dL	3.36–4.11 mmol/L
➢ High	160–189 mg/dL	4.11–4.20 mmol/L
➢ Very high	>190 mg/dL	>4.21 mmol/L
HDL cholesterol		
➢ Low	<40 mg/dL	<1.03 mmol/L
➢ High, protective range	>60 mg/dL	>1.55 mmol/L
Triglycerides	<160 mg/dL	<2.26 mmol/L

(HDL: High-density lipoprotein; LDL: Low-density lipoprotein)

Renal Function Tests (Table A1.4)

TABLE A1.4: Urea and electrolytes.

	Reference value	
Analyte	***Conventional***	***SI units***
Sodium	136–146 mEq/L	136–146 mmol/L
Potassium	3.5–5.0 mEq/L	3.5–5.0 mmol/L
Chloride	95–107 mEq/L	95–107 mmol/L
Urea	20–40 mg/dL	3.3–6.6 mmol/L
Creatinine	0.6–1.2 mg/dL	53–106 µmol/L

Thyroid Function Tests (Table A1.5)

TABLE A1.5: Thyroid function tests.

		Reference value	
Thyroid function tests	***Specimen***	***Conventional***	***SI units***
Radioactive iodine uptake (RAIU) 24 hours		5–30%	
Thyroxine (T4) total	Serum	5.4–11.7 µg/dL	70–151 nmol/L
Tri-iodothyronine (T3) total	Serum	77–135 ng/dL	1.2–2.1 nmol/L
Thyroid stimulating hormone (TSH)	Serum	0.4–4.25 µg/mL	0.4–4.25 mU/L

Urine (Table A1.6)

TABLE A1.6: Normal urine values.

Component	***Reference value***
Volume—24 hours	600–1,800 mL (variable)
pH	5.0–9.0
Specific gravity, quantitative (random)	1.002–1.028 (average 1.018)
Protein—24 hours urine	<150 mg/day
Protein, qualitative (random)	Negative
Glucose, quantitative—24 hours urine	50–300 mg/day
Glucose, qualitative (random)	Negative
Urobilinogen—24 hours urine	1.0–3.5 mg/day
Microalbuminuria (24 hours)	0–30 mg/24 hours (0–0.03 g/day) (0–30 μg/mg creatinine) (0–0.03 g/g creatinine)

Cerebrospinal Fluid (Table A1.7)

TABLE A1.7: Normal values of cerebrospinal fluid.

	Reference value	
Component	***Conventional***	***SI units***
CSF volume	120–150 mL	
Appearance	Clear and colorless	
CSF pressure	60–150 mm water	
pH	7.31–7.34	
Total proteins	20–40 mg/dL	0.14–0.45 g/L
Glucose	40–80 mg/dL	2.3–4.5 mmol/L
Chlorides	720–750 mg/dL	
Cells		
➢ Polymorphs	Usually absent	
➢ Lymphocytes	0–5/μL	

(CSF: Cerebrospinal fluid)

Short List of Routinely used Formulae in Medicine (Table A1.8)

TABLE A1.8: Short list of routinely used formulae in medicine.

Electrolyte disorders	
Plasma osmolality	2 Na^+ (mEq/L) + serum glucose (mg/dL)/18 + BUN (mg/dL)/2.8
Corrected sodium	Increase Na^+ by 1.6 mEq/L for each 100 mg% of serum glucose (when serum glucose >100 mg%)
Total body sodium deficit	(Desired sodium – measured sodium) x Body weight x [0.6 (men) or 0.5 (women)]
Potassium deficit	1 mmol/L decrease → approximately 200–400 mmol loss of total body K^+
Urine-plasma electrolyte ratio (in chronic hyponatremia)	Urinary (sodium + potassium)/plasma sodium ➢ >1 (fluid restriction up to <500 mL/day) ➢ =1 (500–700 mL/day) ➢ <1 (fluid restriction up to 1 L)
Water deficit (in hypernatremia)	Water deficit = (plasma sodium – 140) x TBW/140
TTKG (trans-tubular potassium gradient) in hypokalemia	Urinary potassium x plasma osmolality/serum potassium x urinary osmolality ➢ >4 indicates renal loss of potassium
Corrected calcium	0.8 x (4 – serum albumin) + serum calcium
Acid-base disorders	
Anion gap (serum)	(Sodium + potassium) – (bicarbonate + chloride) ➢ 8–16 mEq/L (old methods) ➢ 5–11 mEq/L (new techniques)
Urine anion gap	Urine sodium + potassium – chloride ➢ –25 to –50 (normal range)

Contd...

Contd...

Delta ratio	(Serum anion gap – 12)/(24 – serum bicarbonate) ➢ <0.4 hyperchloremic normal anion gap acidosis ➢ <1 high AG and normal AG acidosis ➢ >2 high AG acidosis and a concurrent metabolic alkalosis
Respiratory acidosis	Acute: 10 increase in $pCO_2 \rightarrow$ 1 increase in bicarbonate Chronic: 10 increase in $pCO_2 \rightarrow$ 4 increase in bicarbonate
Respiratory alkalosis	Acute: 10 decrease in $pCO_2 \rightarrow$ 2 decrease in bicarbonate Chronic: 10 decrease in $pCO_2 \rightarrow$ 5 decrease in bicarbonate
Metabolic acidosis	$pCO_2 = 1.5$ (bicarbonate) $+ 8 \pm 2$
Metabolic alkalosis	10 increase in bicarbonate $\rightarrow pCO_2$ increases by 6
Nephrology	
Renal failure index	Urine Na/(Urine Cr/PCr)
Cockcroft-Gault GFR	(140 – Age) × (Body weight in kg) × (0.85 if female)/(72 × Cr)
Fractional excretion of sodium (FENa)	(Serum Cr × Urine Na)/(Serum Na × Urine Cr)%
Hematology	
Corrected reticulocyte count	Reticulocyte % × (Hb/15)
Reticulocyte production index	= Corrected reticulocyte count/maturation time ➢ At a hemoglobin of 15, the maturation time = 1 day ➢ At a hemoglobin of 12, the maturation time = 1.5 days ➢ At a hemoglobin of 8, the maturation time = 2 days ➢ At a hemoglobin of 5, the maturation time = 2.5 days
Mentzer index	(MCV, in fL) divided by (RBC, in millions per µL) ➢ <13, thalassemia is said to be more likely
Parenteral iron in iron deficiency anemia	[2.3 x body weight (kg) x Hb deficit (gm/dL)] + 1,000 mg (to replenish stores)
Respiratory system	
A-a gradient	$PAO_2 - PaO_2$ ($PAO_2 = (FiO_2 \times 713) - PaCO_2/0.8$; PaO_2 is obtained from the ABG)
Cardiology	
Corrected QT	QT interval / √(RR interval) (Bazzett's formula)
MAP	Systolic BP + (2 × diastolic BP)/3
Miscellaneous	
BMI	W/H^2 (W = weight in kg and H = Height in meters)

(BMI: Body mass index; BUN: Blood urea nitrogen; GFR: Glomerular filtration rate; MAP: Mean arterial pressures; MCV: Mean corpuscular volume; RBC: Red blood cells)

Galsulfase 1438
Gamekeepers thumb 672
Gametocytes 409
Gamma hydroxybutyrate 1368
Gamma-aminobutyric acid 600, 1113, 1129
Gamma-glutamyl transpeptidase 550, 589, 1363
Ganglia, basal 629, 1028, 1147
Gardner's syndrome 545
Garland sign 1186
Garland triad 334
Gas exchange function, tests for 194
Gastric
  acid 361
    analysis 514
    hypersecretion 654
  adenocarcinoma 1054
  antral vascular ectasia 708*f*
  carcinoma, higher incidence of 739
  contents
    aspiration of 264, 294
  disorders 1093
  electrical stimulation 488
  emptying 506
  hyperacidity 512
  lavage 496, 1105, 1241, 1263, 1363
  lymphoma, primary 802
  malignancies 514
  mucosa, heterotopic 510
  mucosal blood flow 511
  outflow obstruction 516
  surgery 516
  ulcer 513*t*
    benign 514*f*
    chronic nonhealing 516
  varices 596
Gastrin, elevated fasting 654
Gastrinoma 653
  triangle of Passaro 654, 654*f*
Gastritis
  acute 511*f*
  chronic 511, 511*f*
Gastroenteritis 499
Gastroenterology 487
Gastroesophageal junction 505
Gastroesophageal reflux disease 201, 202, 505, 507*t*, 1114
  development of 506*f*
  management of 505
  signs of 507*t*
  symptoms of 507*t*
  treatment of 507
Gastrointestinal
  bleeding, acute 616
  complications 806, 880, 1107
  decontamination 1254, 1262
  disease 459, 487, 547
  disorders 490, 1114
  involvement 701
  manifestations 428, 459, 707
  motor abnormalities 528
  mucosal toxicity 1465
  procedures 107
  reactions 244
  signs 1238
  symptoms 369, 665, 1041
  system 1007
  toxic plant poisons 1260
  tract 527, 698, 1094, 1303, 1420
    absorption 1441
    functional disorders of 527*t*
    procedure 108
Gastroparesis 982
Gastropathy, congestive 595
Gatifloxacin 243
Gaucher's disease 142, 1438
Gaze apraxia 1126
Gefitinib 1069
Gell and Coombs classification 1403*f*
Geller syndrome 938
Gemcitabine 1067
Gender identity disorder 1369, 1370
Gene 1049
  deficiency 998
  environment interactions 657
  epigenetic modification of 1428
  expression
    profiling 1057
    regulation of 1431
  mapping 1430-1432
  mutation analysis 648
  silencing 1429
  therapy 750, 1428
    forms of 1429
    limitations of 1429
    short-lived nature of 1429
    surgical delivery of 1210
    therapeutic application of 1430*t*
    types of 1429
    vectors in 1429
  tumors in 1049
Genetic
  alteration, analysis of 1434
  anticipation 1427

  mutations 1431
  polymorphism 435, 1439*t*
  predisposition 309, 651, 657, 1053, 1053*t*, 1307
  susceptibility 943, 1013
  syndromes 938, 938*t*, 940*f*
  testing 628
    indications of 1434*t*
Genital herpes 463*f*
Genital lesions 1325*f*, 1331
Genital ulcer 700
  disease 1335
    causes of 1335*t*
    differential diagnosis of 1336*t*
Genital warts 463*f*
  penis 1054
  vulva 1054
Genitalia 1422
  external 383*f*, 1329
Genitourinary system 467
Genitourinary tract
  infections 469
  procedure 108
Genome-wide association studies 657, 945, 1435
Gentamicin 358
Gepirone 1345
Geriatric 1265, 1265*f*
  giants 1269, 1270*f*
  psychiatry 1372
Germ cell therapy 1429
German measles 376
Germline
  gene therapy 1429
  mutation testing, indications for 1434

Gerontology 1265, 1265*f*
Gerstmann's syndrome 1140
Gestational diabetes mellitus 942, 983, 983*b*, 984*b*
  diagnosis of 984, 984*b*, 984*t*
Ghon complex 232
  fate of 232
Ghon focus 232
Ghon lesion 232
Ghrelin 1112
Gianotti-Crosti syndrome 379
Giant
  bullae, ablation of 226
  cell arteritis 697, 702, 703*t*
  metamyelocytes 741
  platelets 786
Giardia
  intestinalis 524
  lamblia 364, 524
Giardiasis 524
  acute 524
  chronic 524
  treatment of 524
Gibraltar, rock fever of 367
Giddiness 244
Gilbert's syndrome 558, 559
Ginger Jake paralysis 1245
Gingival hyperplasia 769*f*
Ginkgo biloba 1273
Gitelman syndrome 939
Glands, epithelial component of 1044
Glasgow coma scale 1215, 1215*t*, 1474
Glasgow criteria, modified 644, 645*b*
Glecaprevir 575
Gliptins 958
Glomerular basement membrane 863, 865-867, 903, 976
Glomerular capillary wall 866, 868
Glomerular diseases 861, 862, 903
  causes of 861*b*
  primary 868
  spectrum of 862*fc*
  syndromes of 861*b*
Glomerular filtration 844
  rate 605, 845, 853, 876*f*
Glomerulonephritis 410, 630, 699, 861, 862, 881, 1396
  acute 863, 866*f*
  causes of 861
  chronic 861
  crescentic 864
  focal segmental 104, 108, 848, 861, 863
  postinfectious 863
  primary 861
  rapidly progressive 864
Glomerulopathy, primary 861
Glomerulosclerosis, focal 868, 870
Glomerulus apparatus 843*f*
Glossitis 492
  atrophic 733, 733*f*
  causes of 492
Glottis, spasm of 488
Glucagon 974
Glucagon-like peptide 955
  analogs 958
  receptor 581, 956
Glucagonoma 520, 654
  syndrome 654
Glucocorticoids 337, 488, 578, 676, 698, 699, 1005, 1010, 1019, 1030, 1061, 1071, 1312
  adverse effects of 1040*t*
  deficiency 1037
  doses of 1039*t*
  equivalent doses of 1039
  remediable aldosteronism 938
  systemic 1299
Glucocorticosteroid 541
Glucokinase 941, 948
Glucose 850, 946, 1090, 1170, 1234
  6-phosphate dehydrogenase 754
    deficiency 412, 754
    role of 754*f*
  control 437
  dependent insulinotropic polypeptide 957
  detectable amounts of 951
  homeostasis 947*f*
  intolerance 983
    mild 1041
    phase of impaired 944
  intravenous 842
  management indicator 967
  monitoring, continuous 968
  tolerance test 521, 950*t*
  utilization of 972
Glucuronosyltransferase 559
Glutamate 1234, 1344
Glutamic acid residue, replacement of normal 747
Glutamine 603, 1234
Gluten-sensitive enteropathy 1300, 1397
Glycemic therapy 882
Glyceraldehyde-3-phosphate dehydrogenase 976
Glyceryl trinitrate 36
  topical 168
Glycolysis, reduced 946, 985

  secondary 1147
  site of 826
  splinter 190
  subconjunctival 104*f*
  subhyaloid 1151
  subperiosteal 1098
  treatment of 826*t*
Hemorrhagic death 821
Hemorrhagic pleural effusion 273
  causes of 273, 273*t*
Hemorrhagic stroke 1136, 1153*t*
  management of 1146, 1148
  pathogenesis of 1135
  surgery in 1149
  surgical treatment for 1149
Hemosiderin 730
Hemosiderosis 752
Hemostasis 814
  components of 814
  mechanisms of 814, 815, 816*f*
  screening tests for 818
Hemostatic plug 815
Hemothorax 268, 273
  causes of 273
Henipavirus 401
Henle, loop 905
Henoch-Schönlein purpura 701, 701*f*, 861, 866, 903
Heparin 808
  antidote of 808
  therapy, complications of 809
  unfractionated 46, 47, 176, 808
Hepatic artery angiography 622
Hepatic coma
  causes of 576
  treatment of 576
Hepatic disease, serologic evidence of 568
Hepatic dysfunction 117
Hepatic encephalopathy 583, 584, 588, 592, 595, 597, 599, 600*t*, 602, 633
  acute 601
  causes of 600
  features of 576
  management of 599, 605*fc*
  precipitating factors for 600
  treatment of 603, 603*f*
  types of 601, 601*fc*
Hepatic failure
  fulminant 576, 599
  pathology of fulminant 576
  subacute 576
Hepatic fibrosis 589*t*
  congenital 885
  measurement of 591
Hepatic glucose output 972
Hepatic impairment 1443
Hepatic insufficiency 585
  symptoms of 585
Hepatic lymph, percolation of 608
Hepatic synthetic function 551
  excellent marker of 551
Hepatic vasculature
  destruction of 584
  distortion of 584
Hepatic vein
  obstruction 620
  occlusion 621
Hepatic venous outflow tract obstruction 619
  clinical features of 619
  etiology of 619
  investigations of 619
  management of 619
Hepatic venous pressure gradient 590, 592
Hepatitis 241, 244, 561, 562, 633
  A 364, 561, 565, 568, 1412
    clinical features of 564
  A infection
    clinical features of 561
    investigations of 561
    management of 561
    treatment of 568
  acute 561, 566*f*, 568, 569
  alcoholic 581, 582
  autoimmune 569
  B 461, 480, 561, 562, 566, 882, 1054, 1412
    clinical features of 564
    coinfection 476
    extrahepatic manifestations of 574
    inactive chronic 570
    mode of transmission of 562
    postexposure prophylaxis for 482, 483
    treatment of chronic 571, 572*b*
  B core antigen 562
    antibody against 566
  B E antigen 566, 574
    antibody against 566
  B infection
    complications of 562
    management of 562
    pathology of chronic 568
    prevention of chronic 568
  B surface antigen 562, 566, 567, 698
    antibody against 566
  B vaccine 1055
  B virus 483*t*, 561, 566*f*, 574, 622
    genome of 562
    infection 574, 574*t*
